Abstract

Advanced plate models with variable kinematics for steady state hygrothermal analysis of composite laminates are proposed. The refined models discussed include both Layer-Wise (LW) and Equivalent Single Layer (ESL) models, and the Carrera Unified Formulation (CUF) is used. The Mixed Interpolation of Tensorial Component (MITC) method is applied to a nine-node element to contrast the shear locking phenomena. The governing equations are derived from the Principle of Virtual Displacement (PVD) taking into account elastic mechanical, thermal and hygroscopic effects. Through-the-thickness variations of temperature and moisture concentration are calculated by solving the Fourier equation and the Fick law, respectively. Cross-ply plates with symmetrical lamination and simply supported edges subjected to bisinusoidal thermal/hygroscopic loads are analyzed considering various thickness ratios. Results obtained with assumed linear and calculated temperature/hygroscopic profiles are compared. Variable kinematics with a variety of thickness functions are compared regarding both accuracy and computational costs. The results show that all the kinematics proposed can approximate the transverse shear stress distribution through the thickness with satisfactory accuracy when sufficient expansion terms are adopted. In some cases, miscellaneous expansions can lead to significant reductions in computational costs. The results here presented can be used as benchmark solutions for future works.

Introduction

Laminated structures like composite plates have been widely used in aerospace engineering. Such structures often undergo environmental conditions, e.g. high temperature, and humidity. Hygrothermal effects can lead to the reduction in both constitutive properties and strength of fiber reinforced polymer composites [1, 2]. The possible high hygrothermal residual stress state is also a serious issue in the design of laminated composite structures. Efficient mechanical models with the ability to capture the hygrothermal elastic behaviors of multilayered structures are of great significance. Closed form analytical solutions are only available in several cases, making numerical methods such as FEM the first choice for engineering applications.

Studies on thermal elastic behaviors of composite laminates have been reported by many authors. With the linear temperature profile assumption, Kant [3] and Khdeir [4] considered this problem with first-order theories. The significance of mixed models for accurate estimations of transverse shear/normal stresses under thermal load has been remarked in [5] and [6].
The thermal conduction in solid media can be described by the Fourier equation, which can be solved by adopting the methodology proposed by Tungikar [7]. Concerning thermal elastic analysis of composite laminates, Carrera [8] exploited the partially coupled thermal elastic governing equations and discussed the influence of through-the-thickness variation of temperature by comparing the thermal mechanical response of laminated anisotropic plates; in particular, assumed profiles and calculated profiles obtained by solving the Fourier conduction equation were used. For thin laminated structures, calculated steady state through-the-thickness temperature profiles can be very close to an assumed linear one, while this is not the case for thick laminates [8]. Fully coupled thermo mechanical analyses on laminated plates can be found in [9].

Following Fourier’s work [10], Fick pointed out that the diffusion of moisture in solid media follows the same rule as heat does [11]. Moreover, researchers pointed out that thermal conduction coefficients and humidity diffusivity depend on the temperature [2]. Generally speaking, there is an interaction between thermal environment and moisture diffusion[2], but the temperature approaches equilibrium much faster than moisture concentration [12, 13]. By considering the analogy between thermal conduction and moisture diffusion, Szekeres et al. [14, 15] suggested that the methodology used to solve the Fourier equation [7] can be extended to hygroscopic problems, which has been the basis of many later works.

Benkeddad [16, 17] studied the moisture diffusion process in composite plates by taking only the thickness dimension into consideration, leading to a 1D diffusion problem, and the moisture concentration at a given moment was determined by finite difference method. A similar methodology was adopted for the analysis of transient hygroscopic stresses in unidirectional laminated composite plates with cyclic and asymmetrical environmental conditions by Tounsi et al. [18, 21]. Abbas [22] and Boukhoulda [23] introduced the Laplace transform to obtain analytical solutions for transient moisture concentration problems. Patel [24] and Lo et al. [25] considered the variation of material properties due to temperature and moisture variation for the static response analysis of multilayered plates.

Carrera Unified Formulation (CUF) provides a methodology to develop refined models for the analysis of laminated composite structures, enabling FEM models to have variable kinematics of arbitrary order. Many advanced FEM models have been proposed and applied but not restricted to multifield problems. Carrera [26, 27] proposed advanced finite elements for composite laminates based on CUF using both Equivalent Single Layer (ESL) and Layer-Wise (LW) approaches. Trigonometric trial functions were used in combination with Ritz method in [28].
In authors’ previous works [29], CUF was applied to thermoelastic problems of laminated structures, and their static bending responses under both assumed linear and calculated temperature profiles, obtained by solving the Fourier equation, were reported. The Mixed Interpolation of Tensorial Components (MITC) [30–33] method was implemented to alleviate lockings. Such an MITC9 element with a variety of thickness functions have been used to investigate the static response of cross-ply laminated plates and shells [34].

In this paper, considering the analogy between moisture diffusion and thermal conduction, the approach that has been successfully used in solving heat conduction problems [29] is extended to steady state hygroelastic problems. This study mainly focuses on the performance of variable and miscellaneous kinematics of plate elements in the analysis of hygrothermal problems. For simplicity, it is assumed that the thermal conductivity and mass diffusivity do not change with temperature. Both the thermal and hygroscopic problems are restricted to steady state conditions.

**Geometrical and constitutive relations**

The reference system and the geometry of the multilayered plate are given in Fig. [1]

Considering a multilayered structure, where the index \( k \) indicates the layer, the geometrical relations can be written as:

\[
e_p^k = \begin{bmatrix} \epsilon_{kxx}^k, \epsilon_{kyy}^k, \epsilon_{kxy}^k \end{bmatrix}^T = D_p u^k
\]

\[
e_n^k = \begin{bmatrix} \epsilon_{kxz}^k, \epsilon_{kyz}^k, \epsilon_{kzz}^k \end{bmatrix}^T = (D_{n\Omega} + D_{nz}) u^k
\]

The explicit form of the introduced arrays, that contain differential operators, is:

\[
D_p = \begin{bmatrix} \partial_x & 0 & 0 \\ 0 & \partial_y & 0 \\ \partial_y & \partial_x & 0 \end{bmatrix}, \quad D_{n\Omega} = \begin{bmatrix} 0 & 0 & \partial_x \\ 0 & 0 & \partial_y \\ 0 & 0 & 0 \end{bmatrix}, \quad D_{nz} = \begin{bmatrix} \partial_z & 0 & 0 \\ 0 & \partial_z & 0 \\ 0 & 0 & \partial_z \end{bmatrix}.
\]
Considering the expansion caused by the increase of temperature and moisture absorption, the strain vector can be expressed as follows:

\[
\epsilon_k^p = \epsilon_{pu}^k - \epsilon_{p\theta}^k - \epsilon_{pq}^k = \epsilon_{pu}^k - \alpha_{kp}^k \theta_k - \beta_{kp}^k \eta_k
\]
\[
\epsilon_k^n = \epsilon_{nu}^k - \epsilon_{n\theta}^k - \epsilon_{n\eta}^k = \epsilon_{nu}^k - \alpha_{kn}^k \theta_k - \beta_{kn}^k \eta_k
\]

where \(\alpha_{ij}\) are the thermal expansion coefficients, and \(\beta_{ij}^k\) the moisture expansion coefficients, which in an explicit form are:

\[
\alpha_k^p = \begin{bmatrix} \alpha_{11}^k & \alpha_{12}^k & 0 \\ \alpha_{21}^k & \alpha_{22}^k & \alpha_{26}^k \\ 0 & \alpha_{62}^k & \alpha_{66}^k \end{bmatrix}, \quad \alpha_k^n = \begin{bmatrix} 0 & 0 & \alpha_3^k \end{bmatrix}^T
\]
\[
\beta_k^p = \begin{bmatrix} \beta_{11}^k & \beta_{12}^k & 0 \\ \beta_{21}^k & \beta_{22}^k & \beta_{26}^k \\ 0 & \beta_{62}^k & \beta_{66}^k \end{bmatrix}, \quad \beta_k^n = \begin{bmatrix} 0 & 0 & \beta_3^k \end{bmatrix}^T
\]

\(\theta\) indicates the increment of temperature, and \(\eta\) the moisture absorption. The stress-strain relations are:

\[
\sigma_k^p = \begin{bmatrix} \sigma_{xx}^k, \sigma_{yy}^k, \sigma_{xy}^k \end{bmatrix}^T = \sigma_{pu}^k - \sigma_{p\theta}^k - \sigma_{pq}^k = C_{pp}^k \epsilon_{pu}^k + C_{pn}^k \epsilon_{nu}^k - \lambda_{pu}^k \theta_k - \mu_{pu}^k \eta_k
\]
\[
\sigma_k^n = \begin{bmatrix} \sigma_{xz}^k, \sigma_{yz}^k, \sigma_{zz}^k \end{bmatrix}^T = \sigma_{nu}^k - \sigma_{n\theta}^k - \sigma_{n\eta}^k = C_{np}^k \epsilon_{pu}^k + C_{nn}^k \epsilon_{nu}^k - \lambda_{nu}^k \theta_k - \mu_{nu}^k \eta_k
\]

where

\[
C_{pp}^k = \begin{bmatrix} C_{11}^k & C_{12}^k & C_{16}^k \\ C_{21}^k & C_{22}^k & C_{26}^k \\ C_{61}^k & C_{62}^k & C_{66}^k \end{bmatrix}, \quad C_{pn}^k = \begin{bmatrix} 0 & 0 & C_{13}^k \\ 0 & 0 & C_{23}^k \\ 0 & 0 & C_{63}^k \end{bmatrix}
\]
\[
C_{np}^k = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ C_{13}^k & C_{23}^k & C_{36}^k \end{bmatrix}, \quad C_{nn}^k = \begin{bmatrix} C_{55}^k & C_{45}^k & 0 \\ C_{45}^k & C_{44}^k & 0 \\ 0 & 0 & C_{33}^k \end{bmatrix}
\]

\[
\lambda_k^p = C_{pp}^k \alpha_k^p + C_{np}^k \alpha_k^n
\]
\[
\lambda_k^n = C_{np}^k \alpha_k^p + C_{nn}^k \alpha_k^n
\]

\[
\mu_k^p = C_{pp}^k \beta_k^p + C_{np}^k \beta_k^n
\]
\[
\mu_k^n = C_{np}^k \beta_k^p + C_{nn}^k \beta_k^n
\]

where \(\lambda_k^p\) and \(\lambda_k^n\) are the vectors of thermomechanical coupling coefficients, \(\mu_k^p\) and \(\mu_k^n\) the vectors
of hygromechanical coupling coefficients, which in an explicit form are:

\[
\lambda_p^k = \begin{bmatrix} \lambda_{k1}^k & \lambda_{k2}^k & \lambda_{k6}^k \end{bmatrix}^T, \quad \lambda_n^k = \begin{bmatrix} 0 & 0 & \lambda_{k3}^k \end{bmatrix}^T
\] (9)

\[
\mu_p^k = \begin{bmatrix} \mu_{k1}^k & \mu_{k2}^k & \mu_{k6}^k \end{bmatrix}^T, \quad \mu_n^k = \begin{bmatrix} 0 & 0 & \mu_{k3}^k \end{bmatrix}^T
\] (10)

The material coefficients \(C_{ij}\) depend on the Young, shear, and Poisson moduli, see Reddy’s book [35]. The matrix of materials coefficients, as written in Eq. (6), has been already rotated from the material reference system to the global reference system \((x, y, z)\).

### Variable kinematics based on Carrera Unified Formulation

In the framework of CUF, the displacement vector \(u = \{u, v, w\}\) can be expressed utilizing expansion functions as follows:

\[
\begin{align*}
\{u(x, y, z) &= F_0(z)u_0(x, y) + F_1(z)u_1(x, y) + \cdots + F_N(z)u_N(x, y) \\
v(x, y, z) &= F_0(z)v_0(x, y) + F_1(z)v_1(x, y) + \cdots + F_N(z)v_N(x, y) \\
w(x, y, z) &= F_0(z)w_0(x, y) + F_1(z)w_1(x, y) + \cdots + F_N(z)w_N(x, y)
\end{align*}
\] (11)

In a more compact form, CUF can be expressed in the following form for ESL models:

\[
\delta u(x, y, z) = F_\tau(z)\delta u_\tau(x, y); \quad u(x, y, z) = F_s(z)u_s(x, y) \quad \tau, s = 0, 1, \ldots, N
\] (12)

CUF-based LW models can be written as:

\[
\delta u^k(x, y, \zeta_k) = F_\tau(\zeta_k)\delta u^k_\tau(x, y); \quad u^k(x, y, \zeta_k) = F_s(\zeta_k)u^k_s(x, y) \quad \tau, s = 0, 1, \ldots, N
\] (13)

where \(\Omega\) is the in-plane domain, and \(\delta u\) indicates the virtual displacement associated with the virtual work and \(k\) is the index of a layer in the laminated plate. \(F_\tau^{(k)}\) and \(F_s^{(k)}\) are the so-called thickness functions whose independent variable is either \(z\) defined in the whole thickness domain \(z \in [-\frac{h}{2}, \frac{h}{2}]\) for ESL models, or \(\zeta_k\) defined in each layer domain \(\zeta_k \in [-1, 1]\) for LW models. Depending on the type of
expansion functions, $N$ may represent the order of the expansion or the number of expansion terms. $u_s$ represents the unknown primary variables which are the coefficients of corresponding expansion terms, whose independent variables are $x$ and $y$. $\tau$ and $s$ are the indexes of the expansion terms, and the Einstein summation rule is used.

**Higher-Order Theories**

In the case of Equivalent Single Layer (ESL) models, Taylor series expansions can be employed as thickness functions:

$$ u = F_0 u_0 + F_1 u_1 + \ldots + F_N u_N = F_s u_s, \quad s = 0, 1, \ldots, N $$

(14)

$$ F_0 = z^0 = 1, \quad F_1 = z^1 = z, \quad \ldots, \quad F_N = z^N $$

(15)

Classical models, such as those based on the First-Order Shear Deformation Theory (FSDT) \[36, 37\], can be obtained with an ESL approach with $N = 1$, by imposing a constant transverse displacement through the thickness via penalty techniques. Also, a model based on the hypotheses of Classical Lamination Theory (CLT) \[38\] can be expressed employing CUF by applying a penalty technique to the constitutive equations to impose null transverse shear strains.

**Refined ESL models based on trigonometric and exponential series**

In the framework of ESL models, if trigonometric sine series with a constant term are adopted, the displacement vector can be written as follows:

$$ u(x, y, z) = u_0(x, y) + \sin \left( \frac{\pi z}{h} \right) u_1(x, y) + \ldots + \sin \left( \frac{n\pi z}{h} \right) u_N(x, y) $$

(16)

where $h$ is the thickness of the whole laminated structure and $n$ is the half waves number. If the linear Taylor term is considered, the displacement vector is

$$ u(x, y, z) = u_0(x, y) + z u_1(x, y) + \sin \left( \frac{\pi z}{h} \right) u_2(x, y) + \ldots + \sin \left( \frac{n\pi z}{h} \right) u_{N+1}(x, y) $$

(17)
For trigonometric cosine series,

\[ u(x, y, z) = u_0(x, y) + \cos \left( \frac{\pi z}{h} \right) u_1(x, y) + \ldots + \cos \left( \frac{n\pi z}{h} \right) u_N(x, y) \]  \hspace{1cm} (18)

and with the linear term,

\[ u(x, y, z) = u_0(x, y) + z u_1(x, y) + \cos \left( \frac{\pi z}{h} \right) u_2(x, y) + \ldots + \cos \left( \frac{n\pi z}{h} \right) u_{N+1}(x, y) \]  \hspace{1cm} (19)

Considering the complete trigonometric series,

\[ u(x, y, z) = u_0(x, y) + \sin \left( \frac{\pi z}{h} \right) u_1(x, y) + \cos \left( \frac{\pi z}{h} \right) u_2(x, y) + \ldots + \sin \left( \frac{n\pi z}{h} \right) u_{2N-1}(x, y) + \]

\[ + \cos \left( \frac{n\pi z}{h} \right) u_{2N}(x, y) \]  \hspace{1cm} (20)

If the linear contribution is considered,

\[ u(x, y, z) = u_0(x, y) + z u_1(x, y) + \sin \left( \frac{\pi z}{h} \right) u_2(x, y) + \cos \left( \frac{\pi z}{h} \right) u_3(x, y) + \ldots + \]

\[ + \sin \left( \frac{n\pi z}{h} \right) u_{2N}(x, y) + \cos \left( \frac{n\pi z}{h} \right) u_{2N+1}(x, y) \]  \hspace{1cm} (21)

If exponential series are employed, the displacement field can be expressed as:

\[ u(x, y, z) = u_0(x, y) + e^{(z/h)} u_1(x, y) + \ldots + e^{(nz/h)} u_N(x, y) \]  \hspace{1cm} (22)

and adding the linear term one obtains

\[ u(x, y, z) = u_0(x, y) + z u_1(x, y) + e^{(z/h)} u_2(x, y) + \ldots + e^{(nz/h)} u_{N+1}(x, y) \]  \hspace{1cm} (23)

**Refined ESL models with Murakami zig-zag function**

According to Murakami [39], a zig-zag term can be introduced into Eq. (14) leading to refined ESL zig-zag models,

\[ u = F_0 u_0 + \ldots + F_N u_N + (-1)^k \zeta_k u_Z. \]  \hspace{1cm} (24)
Subscript $Z$ refers to the Murakami zig-zag function. Refined zig-zag models can be obtained by adding the zig-zag term to the Taylor polynomials, trigonometric or exponential series expansions.

**Refined LW models based on Legendre polynomials**

If Legendre polynomials are adopted, the displacement field defined for a layer $k$ can be expressed as

$$ u^k = F_t u^k_t + F_b u^k_b + F_r u^k_r = F_s u^k_s, \quad s = t, b, r, \quad r = 2, \ldots, N. \quad (25) $$

The expansion terms are

$$ F_t = \frac{P_0 + P_1}{2}, \quad F_b = \frac{P_0 - P_1}{2}, \quad F_r = P_r - P_{r-2}. \quad (26) $$

$P_j$ is the $j^{th}$-order Legendre polynomial defined in the $\zeta_k$-domain: $-1 \leq \zeta_k \leq 1$. The displacements on the top ($t$) and bottom ($b$) surfaces are used as unknown variables and one can impose the following compatibility conditions at the interfaces:

$$ u^k_t = u^{k+1}_b, \quad k = 1, N_l - 1. \quad (27) $$

The employment of hierarchical Legendre polynomials as basis functions for the development of variable kinematic models was presented by Szab, Dster, and Rank [40]. Other implementations of Legendre polynomials in the framework of CUF can be found in [41–43].

**Refined LW models adopting Sampling Surfaces method (SaS)**

Kulikov [44–46] proposed the Sampling Surfaces method (SaS) as an LW model based on Lagrange interpolation polynomials. Within each layer, an arbitrary number of sampling surfaces parallel to the middle surface are introduced. Each SaS is located at a Lagrange interpolation point, and the displacements at these points are taken as primary unknowns. The present work implements the SaS technique for the plate element based on CUF. In SaS, the displacement field can be defined as

$$ u^k = F_0 u^k_0 + F_1 u^k_1 + \ldots + F_N u^k_N = F_s u^k_s, \quad s = 0, 1, \ldots, N. \quad (28) $$
\( F_s(\zeta_k) \) (thickness function) is a Lagrange polynomial of order \( N \),

\[
F_s(\zeta_k) = \prod_{i=0,i\neq s}^{N} \frac{\zeta_k - \zeta_{k_i}}{\zeta_k - \zeta_i}
\]

(29)

\( \zeta_k \) are located at the prescribed interpolation points. \( \zeta_{k_0} = -1 \) and \( \zeta_{k_N} = 1 \) correspond to the top and bottom positions of the \( k^{th} \) layer, respectively.

**Through-the-thickness variation of temperature and moisture concentration**

The temperature variation through the thickness can be obtained by solving Fourier heat conduction equation as described in [7] for multilayered plates. If the temperature on the top and bottom surfaces are given, a priori assumed linear temperature variation profile through-the-thickness can be obtained as follows:

\[
\theta(z) = \theta_t + \frac{\theta_t - \theta_b}{h} \cdot (z + \frac{h}{2})\quad z \in [-\frac{h}{2}, \frac{h}{2}]
\]

(30)

where the subscripts \( b \) and \( t \) refer to the bottom and top surfaces, respectively. It is evident that the temperature continuity between two layers can be naturally guaranteed in this manner. Similarly, an assumed linear moisture concentration profile could be described as:

\[
\eta(z) = \eta_t + \frac{\eta_t - \eta_b}{h} \cdot (z + \frac{h}{2})\quad z \in [-\frac{h}{2}, \frac{h}{2}]
\]

(31)

Alternatively, a more physically meaningful profile can be obtained by solving Fourier heat conduction equation for temperature variation, or the Fick law for moisture concentration distribution. In multilayered plate structures, for the \( k^{th} \) homogeneous orthotropic layer, the Fourier differential equation for heat conduction problems reads:

\[
K_1^k \frac{\partial^2 \theta}{\partial x^2} + K_2^k \frac{\partial^2 \theta}{\partial y^2} + K_3^k \frac{\partial^2 \theta}{\partial z^2} = 0
\]

(32)

where \( K_1^k, K_2^k \) and \( K_3^k \) are the thermal conduction coefficients in material coordinates (1,2,3) for the \( k^{th} \) layer and will be rotated to the general reference system \((x, y, z)\). In the \( k^{th} \) layer, \( K_1^k, K_2^k \) and \( K_3^k \) are assumed to be constants. The relationship between the temperature \( \theta \) and the transverse normal
heat flux \( q_z \) is described by
\[
q_z^k = K^3 \frac{\partial \theta}{\partial z} \tag{33}
\]
For multilayered structures, continuity conditions of \( \theta \) and \( q_z \) holds in the thickness direction at each layer interface, reading:
\[
\theta^k_t = \theta^{k+1}_b, \quad q_z^k = q_z^{k+1}_b \quad k = 1, \ldots, N_l - 1 \tag{34}
\]
where \( N_l \) is the number of layers in the composite laminate. In this work, the governing equation and boundary conditions are satisfied in each layer by assuming the following temperature field:
\[
\theta(x, y, z) = \theta_A(z) \cdot \theta_\Omega(x, y) \tag{35}
\]
where, for the cases studied in this paper, \( \theta_\Omega \) has a bisinusoidal form as follows:
\[
\theta_\Omega(x, y) = \sin\left(\frac{m \pi x}{a}\right) \cdot \sin\left(\frac{n \pi y}{b}\right) \tag{36}
\]
For the solution of the Fourier heat conduction equation, the reader can refer to the authors’ previous works [29, 47, 48]. Calculated moisture concentration profiles can be acquired by solving the Fick law, which postulates that the flux \( J \) goes from regions of high concentration to areas of low concentration, with a diffusion rate that is proportional to the concentration gradients (spatial derivatives). For a steady state plate structure, the Fick second law can be expressed as
\[
D^1_k \frac{\partial^2 \eta}{\partial x^2} + D^2_k \frac{\partial^2 \eta}{\partial y^2} + D^3_k \frac{\partial^2 \eta}{\partial z^2} = 0 \tag{37}
\]
where \( D^1_k, D^2_k \) and \( D^3_k \) are the diffusion coefficients (diffusivity) and \( \eta \) is the moisture concentration. Accordingly, moisture concentration \( \eta \) and diffusion flux through the thickness \( J_z \) can be related by
\[
J_z^k = D^3_k \frac{\partial \eta}{\partial z} \tag{38}
\]
and the continuity of \( \eta \) and \( J_z \) at layer interfaces can be imposed as
\[
\eta^k_t = \eta^{k+1}_b, \quad J_z^k = J_z^{k+1}_b \quad k = 1, \ldots, N_l - 1 \tag{39}
\]
Similarly to the thermal case, the 3D hygroscopic field can be described as

$$\eta(x, y, z) = \eta_A(z) \cdot \eta_\Omega(x, y) \quad (40)$$

If a bisinusoidal load is imposed,

$$\eta_\Omega(x, y) = \sin\left(\frac{m\pi x}{a}\right) \cdot \sin\left(\frac{n\pi y}{b}\right) \quad (41)$$

As discussed above, the Fick law can be solved in analogy with the Fourier heat conduction equation under given hygroscopic boundary conditions on the top and bottom surfaces of the laminated structures.

**MITC9 finite element and governing equations**

This section presents the derivation of the finite element stiffness matrix based on the Principle of Virtual Displacement (PVD) in the case of multilayered plates under hygrothermal environmental load. A nine-node element adopting the Mixed Interpolation of Tensorial Component (MITC) method is formulated in the framework of CUF. The displacement vector interpolated on the element nodes utilizing Lagrangian shape functions $N_i$ reads

$$\delta u_\tau = N_i \delta U_{\tau_i}, \quad u_s = N_j U_{s_j} \quad i, j = 1, \ldots, 9 \quad (42)$$

$U_{s_j}$ and $\delta U_{\tau_i}$ are the nodal displacement vector and its virtual variation, respectively. Therefore, the strain expression (Eq. (3)) becomes

$$\begin{cases} 
\epsilon_p = F_s D_p N_j U_{s_j} \\
\epsilon_n = F_s D_{n\Omega} N_j U_{s_j} + F_{s_z} N_j U_{s_j} 
\end{cases} \quad (43)$$

To contrast the shear locking of thin plates, a specific interpolation strategy according to MITC method is used to derive the strain components on the nine-node element, and the corresponding interpolation points (tying points) are illustrated in previous authors’ works related to the use of the MITC9 element based on the CUF [49–52].

Considering the constitutive equations (Eq. (5)) and the strain vectors (Eq. (43)), scalar temperature
field $\theta$ as well as moisture concentration field $\eta$, by applying PVD, one obtains the expression of the internal work for partially coupled hygrothermal problems:

$$\delta L_{\text{int}} = \int_{\Omega} \int_{A_k} \delta \epsilon^T \sigma^k \, d\Omega \, dz = \int_{\Omega} \int_{A_k} \left[ \delta \epsilon^T_p (\sigma_{p \nu}^k - \sigma_{p \theta}^k - \sigma_{p \eta}^k) + \delta \epsilon^T_n (\sigma_{n \nu}^k - \sigma_{n \theta}^k - \sigma_{n \eta}^k) \right] d\Omega \, dz = \delta L_{\text{ext}}$$

(44)

where $A_k$ is the thickness domain of layer $k$ of the plate. $\delta L_{\text{int}}$ represents the variation of the internal work, while $\delta L_{\text{ext}}$ is the external work. Noting that in this work no mechanical loads are considered, which means that $\delta L_{\text{ext}} = 0$, and the internal work $\delta L_{\text{int}}$ is caused purely by the mechanical expansion related to temperature rise and moisture absorption, thus the following expression can be obtained:

$$\int_{\Omega} \int_{A_k} (\delta \epsilon^T_p \sigma_{p \nu}^k + \delta \epsilon^T_n \sigma_{n \nu}^k) \, d\Omega \, dz = \int_{\Omega} \int_{A_k} (\delta \epsilon^T_p \sigma_{p \theta}^k + \delta \epsilon^T_n \sigma_{n \theta}^k) \, d\Omega \, dz + \int_{\Omega} \int_{A_k} (\delta \epsilon^T_p \sigma_{p \eta}^k + \delta \epsilon^T_n \sigma_{n \eta}^k) \, d\Omega \, dz$$

(45)

By substituting the constitutive equations (Eq. (5)), the geometrical relations (Eq. (43)) after the application of MITC method, the displacement expression (Eqs. (12) and (13)) and the FEM discretization (Eq. (42)), the following governing equations can be obtained:

$$\delta U^k_i : K^{k \tau \sigma ij}_{\nu \nu} U^k_{\sigma j} = \Theta^{k \tau \iota} + H^{k \tau \iota}$$

(46)

The $3 \times 3$ matrix $K^{k \tau \sigma ij}_{\nu \nu}$ is the fundamental mechanical nucleus, which is the core unit of the stiffness matrix according to CUF, and its explicit expression is given in [53] for shells (plate is a particular case of shell for radii of curvature tending to infinite). The stiffness matrix of the structure can be obtained by applying the Einstein summation rule, then assembling the fundamental nucleus at laminate level in the framework of either ESL or LW models and at element level considering the nodes. Finally, the global stiffness matrix is assembled using the connectivity matrix. $\Theta^{k \tau \iota}$ and $H^{k \tau \iota}$ are the equivalent thermal and hygroscopic load vectors, and their explicit expressions are given in Eq. (47) and Eq. (48), respectively:

$$\Theta^{k \tau \iota} = \begin{pmatrix}
\Theta^{k \tau \iota}_{xx} \\
\Theta^{k \tau \iota}_{xy} \\
\Theta^{k \tau \iota}_{xz}
\end{pmatrix} = \begin{pmatrix}
\lambda_{6}^k \theta \theta \theta W^\theta \\
\lambda_{1}^k \theta \theta \theta W^\theta \\
\lambda_{2}^k \theta \theta \theta W^\theta \\
\lambda_{3}^k \theta \theta \theta W^\theta
\end{pmatrix}$$

(47)
\[ H^{kr_i} = \begin{bmatrix} H_x^{kr_i} \\ H_y^{kr_i} \\ H_z^{kr_i} \end{bmatrix} = \begin{bmatrix} \mu_6^k J^{\eta_{kr} i} W_{i,y}^\eta + \mu_1^k J^{\theta_{kr} i} W_{i,x}^\theta \\ \mu_2^k J^{\eta_{kr} i} W_{i,y}^\eta + \mu_6^k J^{\theta_{kr} i} W_{i,x}^\theta \\ \mu_3^k J^{\eta_{kr} i} W_{i,y}^\eta \end{bmatrix} \] (48)

\[ W_i, W_{i,x}, W_{i,y} \] are the integrals in the in-plane domain \( \Omega \) and \( J^{\theta_{kr}} \) and \( J^{\eta_{kr} z} \) are the integrals defined within the through-the-thickness domain \( A_k \) of the layer,

\[
\begin{align*}
W_i^\theta &= \int_\Omega N_i \theta dxdy, \quad W_{i,x}^\theta = \int_\Omega \frac{\partial N_i}{\partial x} \theta dxdy, \quad W_{i,y}^\theta = \int_\Omega \frac{\partial N_i}{\partial y} \theta dxdy \\
J^{\theta_{kr}} &= \int_{A_k} F_\tau \theta_k dz, \quad J^{\eta_{kr} z} = \int_{A_k} \frac{\partial F_\tau}{\partial z} \eta_k dz
\end{align*}
\] (50)

\[
\begin{align*}
W_i^\eta &= \int_\Omega N_i \eta dxdy, \quad W_{i,x}^\eta = \int_\Omega \frac{\partial N_i}{\partial x} \eta dxdy, \quad W_{i,y}^\eta = \int_\Omega \frac{\partial N_i}{\partial y} \eta dxdy \\
J^{\eta_{kr}} &= \int_{A_k} F_\tau \eta_k dz, \quad J^{\eta_{kr} z} = \int_{A_k} \frac{\partial F_\tau}{\partial z} \eta_k dz
\end{align*}
\] (51)

\( \theta \) and \( \eta \) denote thermal and hygroscopic cases, respectively. \( F_\tau \) refers to a general expansion term in the displacement field according to CUF, and \( N_i \) represents the shape function corresponding to node \( i \) in the finite element. For more details, the reader can refer to [26, 29, 53].

**Results**

The numerical analysis of this work focuses on investigating the capability of a variety of models with variable kinematics in the analysis of cross-ply symmetrically laminated multilayered structures under hygrothermal environmental loads. This section consists of two numerical cases:

- A three-layer \((0^\circ/90^\circ/0^\circ)\) square plate under thermal load;
- A three-layer \((0^\circ/90^\circ/0^\circ)\) square plate under hygroscopic load.

Acronyms are used to indicate the various models used. For ESL, Table 1 shows all the cases used in this paper.
For example, “ES2C2” and “ET1Exp2Z” refer to the following expansions,

\[ \mathbf{u}^k(x, y, z) = \mathbf{u}_0^k(x, y) + \sin \left( \frac{\pi z}{h} \right) \mathbf{u}_1^k(x, y) + \cos \left( \frac{\pi z}{h} \right) \mathbf{u}_2^k(x, y) + \sin \left( \frac{2\pi z}{h} \right) \mathbf{u}_3^k(x, y) + \cos \left( \frac{2\pi z}{h} \right) \mathbf{u}_4^k(x, y) \] (53)

\[ \mathbf{u}^k(x, y, z) = \mathbf{u}_0^k(x, y) + z\mathbf{u}_1^k(x, y) + e^{\frac{k}{R}} \mathbf{u}_2^k(x, y) + e^{\frac{2k}{R}} \mathbf{u}_3^k(x, y) + (-1)^k \zeta_k \mathbf{u}_4^k \] (54)

The subscript \( a \) denotes the adoption of assumed linear temperature or moisture concentration profiles, whereas \( c \) indicates that through-the-thickness distributions are calculated by via Fourier or Fick laws.

LW models are indicated as follows:

- “SaSn” indicates a Sampling Surfaces model with \( n \) interpolation points.
- “LGDn” indicates a model adopting Legendre polynomials up to the \( n^{th} \) order.

Analytical solutions are used in some cases and obtained via the Navier method. In the following tables, \( N_{exp} \) is indicated and represents the expansion terms of the model.

**Square orthotropic symmetrically laminated plates under thermal load**

Bending of a simply supported cross-ply square composite plate under thermal load is analyzed. The reference solutions were proposed by Bhaskar et al. \[54\], in which thermal analysis was carried out with assumed linear temperature profiles. The composite square plates analyzed have three layers with lamination sequence of \((0^\circ/90^\circ/0^\circ)\). The 3D temperature field is given by

\[ \theta(x, y, z) = \theta_A(z) \cdot \sin \left( \frac{m\pi x}{a} \right) \sin \left( \frac{n\pi y}{b} \right) \] (55)

with bisinusoidal in-plane distribution \((m = n = 1)\). The temperature variation through the thickness is depicted with \( \theta_A(z) \), and the thermal boundary conditions are assumed to be \( \hat{\theta}_A \left( \frac{h}{2} \right) = 1K, \hat{\theta}_A \left( -\frac{h}{2} \right) = -1K \). The physical properties of the composite lamina are given in Table\[2\] in which \( L \) and \( T \) refer to the direction parallel and perpendicular to the fiber direction, respectively. The geometrical dimensions are \( a = b = 1 \), laminates with \( a/h = 2, 10 \) and \( 100 \) were studied, and the three layers have the same thickness. Deflections and stresses are adimensionalized as,

\[ \bar{w} = \frac{w}{h \alpha L \theta_A S^2}, \quad \bar{\sigma}_{ii} = \frac{\sigma_{ii}}{E_T \alpha L \theta_A}, \quad \bar{\sigma}_{ij} = \frac{\sigma_{ij}}{E_T \alpha L \theta_A}, \quad S = a/h \] (56)
where \( i, j = x, y, z \).

First, a mesh convergence study was considered with LGD4, \( a/h = 100 \), and an assumed linear temperature profile. According to the results shown in Table 3, a mesh of \( 10 \times 10 \) is sufficient to ensure the convergence of FEM solution with satisfactory accuracy. The results also show that the adopted MITC9 element is locking free for thin plates.

LW models were considered first. Table 4 presents the obtained displacement and stress values. Moreover, \( N_{exp} \) indicates the number of expansion terms of each model. The calculated temperature variation through the thickness is in Fig. 2. Stress distributions through the thickness are given in Fig. 3. The influence of the expansion terms is shown in Table 4. The results suggest that:

- A perfect match with [54] is found.

- As known, an assumed linear variation of temperature through the thickness leads to satisfactory results in the case of a thin plate. On the other hand, such an assumed profile should not be used for thick plates.

Various ESL models were then investigated with calculated temperature variation profiles. ETn models were first assessed as in Table 5. Since FSDT is not a complete linear case, its number of expansion terms was denoted as “2∗”. It can be stated that:

- For thick plates, nine expansion terms are necessary, while for moderate thick and thin plates, six terms are enough.

- Compared with the computational costs of LGD4 and SaS5, the present ESL kinematics are more efficient for moderate thick and thin plates.

- More often than not, FSDT failed to provide proper displacement and stress evaluations.

ESL models with exponential expansions are considered in Table 6. It can be observed that:

- Stress results are less accurate than the previous cases.

- The addition of the linear Taylor term gives some improvements, but still unsatisfactory accuracies were obtained.
Table 7 show the results from ESL trigonometric expansions. The results show that:

- For thick plates, $\sigma_{xz}$ requires ES5C5Z or ET1S3C3Z. However, the latter is preferable due to fewer expansion terms required.

- For moderately thick and thin plates, ES$n$C$n$Z can provide desired approximations but are more cumbersome than ET$n$Z. The addition of a first-order Taylor term, i.e. using ET1SnC$n$Z, the results improve to a great extend. In particular, ET1S1C1Z gives good accuracy.

Models shown above, are compared in Fig. 4. The transverse shear stress $\bar{\sigma}_{xz}$ is considered for different thickness ratios. It can be found that:

- The use of SaS5 (as well as LGD4) is recommended to capture the transverse shear stress distribution through the thickness.

- As known, the Murakami zig-zag function can improve the transverse shear stress distribution in ESL models.

- Stress distributions obtained with exponential theories are less accurate than the previous cases.

- For thick plates, $\sigma_{xz}$ requires the addition of the linear Taylor term, when trigonometric expansions are used.

In general, the results obtained have demonstrated that ET$n$Z and ET1SnC$n$Z models perform extremely well. Based on the study above, ET$n$Z and ET1SnC$n$Z are chosen for the hygrothermal analysis in the following study cases.

**Square orthotropic symmetrically laminated plates under hygroscopic load**

Square cross-ply laminated plates with stacking sequence ($0^\circ/90^\circ/0^\circ$) subjected to hygroscopic loads are analyzed. The dimensions are $a = b = 0.1m, a/h = 2, a/h = 10$, and $a/h = 100$. The mechanical and hygroscopic properties of the lamina are listed in Table 8 and Table 9 respectively. Moisture expansion coefficients $\beta_{11}, \beta_{22},$ and $\beta_{33}$ were retrieved from [55]. Moisture diffusion coefficients $D_{11}, D_{22},$ and $D_{33}$ were chosen and set under temperature 300 K as in [13]. Hygroscopic loads are defined as:

$$\eta(x, y, z) = \eta_A(z) \cdot \sin\left(\frac{m \pi x}{a}\right) \sin\left(\frac{n \pi y}{b}\right)$$  \hspace{1cm} (57)
where $\eta_A(z)$ describes the moisture concentration profile, $m = n = 1$, and the moisture concentration conditions are $\eta_A(-\frac{b}{2}) = 0$ and $\eta_A(\frac{b}{2}) = 1\%$.

LW models were considered first. Moisture concentration profiles are shown in Fig. 5. Displacement and stress distributions are presented in Fig. 6, in which for the convenience of illustration, the stresses are amplified by 50 times in the plots when necessary, denoted by “*50”. Table 10 summarizes the displacement and stress evaluation on a specific set of monitoring points. The results show that:

- LW models provide highly accurate results.
- As seen in the thermal case, for moderately thick and thin plates, linear profiles are enough. On the other hand, thick plates require calculated profiles.

ET$nZ$ and ET$1SnCnZ$ were then considered, as shown in Fig. 7. The results suggest that, in the case of hygroscopic loads, these models are less accurate than in the case of thermal loads, and LW should be preferred.

**Conclusions**

In the framework of the Carrera Unified Formulation, it is possible to integrate various and miscellaneous approximation theories to obtain refined and advanced models with various kinematics and an arbitrary number of expansion terms for the analysis of multilayered structures. In this paper, steady state mechanical responses of composite plates under thermal/hygroscopic loads are studied with CUF-based variable kinematics adopting LW and ESL approaches, respectively. A MITC9 element is employed to guarantee locking free FEM analysis. Both assumed linear temperature/moisture concentration profiles through the thickness, and calculated variations (by solving the diffusion law) are considered. The analogy between heat conduction and moisture diffusion plays a key role when extending the analysis methodology of thermoelastic problems to hygrothermal ones. Hygrothermal analysis has been carried out on multilayered composite plates. Transverse displacement and stresses are reported for various aspect ratios. The convergence rates of various kinematics are compared. Based on the above work, some conclusions can be drawn as:

1. With a sufficient number of expansion terms, most of the kinematics studied can achieve a good approximation of displacements and stresses with satisfactory accuracy, even for thick plates, and
the expansion number needed depends on the cases studied.

2. For laminates with various aspect ratios, the numbers of expansion terms necessary to obtain converged numerical results are usually different, and thick laminates need more expansion terms.

3. When applied to hygrothermal analysis, classical theory FSDT gives incorrect results even for thin laminates.

4. For thin laminates, linear variation of temperature/moisture concentration through the thickness is a sufficient assumption, whereas for thick layered plates this assumption can lead to overestimated stress evaluation compared with results using profiles obtained by solving Fourier heat conduction equation or Fick Law.

5. For the hygrothermal cases studied, LW models employing Legendre polynomials of the fourth-order (LGD4) and the Sampling Surfaces method with five interpolation nodes (SaS5) can guarantee continuous transverse shear stress distribution through the thickness for composite laminates with a broad range of length to thickness ratios (from 2 to 500).

6. Variable ESL kinematics $ET_nZ$ and $ET1SnCnZ$ have been tested. It has been demonstrated that when a sufficient number of expansion terms are used, with the help of the Murakami zig-zag function, $ET_nZ$, and $ET1SnCnZ$ are capable of capturing transverse shear stress distribution through the thickness of the three-layer plates under symmetrical load. In some cases, these two classes of ESL kinematics can be more computationally efficient than LW models with comparable accuracy. However, for the three-layer plates under unsymmetrical load, ESL models are less efficient in capturing the zig-zag effects.

7. Compared with ESL models, LW models can provide results with better accuracy in approximating the through the thickness distribution of transverse shear stresses in composite laminates.

A companion work to this one is devoted to the modelling of doubly-curved composite shells with antisymmetric lamination subjected to hygrothermal loads. In that paper, very similar conclusions about the accuracy of the models used are drawn.

Future works should be devoted to the axiomatic/asymptotic analysis of the influence of each term and the definition of Best Theory Diagrams, as in [56].
