Abstract

Assessing the quality of an evolving knowledge base is a challenging task as it often require to identify correct quality assessment procedures. Since data is often derived from autonomous, and increasingly large data sources, it is impractical to manually curate the data, and challenging to continuously and automatically assess their quality. In this paper, we explore two main areas of quality assessment related to evolving knowledge bases: (i) identification of completeness issues using knowledge base evolution analysis, and (ii) identification of consistency issues based on integrity constraints. Such as minimum and maximum cardinality, and range constraints. For completeness analysis, we use data profiling information from consistency checks to validate the results of the completeness measures that allow predicting quality issues. This, we perform consistency checks to validate the results of the completeness analysis using integrity constraints and learning models. The approach has been tested both quantitatively and qualitatively by using a subset of datasets from both DBpedia and 3cixty would be bases. The performance of the approach is evaluated using precision, recall, and F1 score. From completeness and such assessed the performance of our consistency analysis by using five learning models over three sub-tasks, namely minimum cardinality, maximum cardinality, and range constraint. We observed that the best performing model in our experimental setup is the Random Fore. Treaching an F1 score greater than 90% for minimum and maximum cardinality and 84% for range constraints.

Keywords: Quality Assessment, Evolution Analysis, Valitation, Inowledge Base, RDF Shape, Machine Learning

1. Introduction

In recent years, numerous efforts have been put to, ords sh .ring Knowledge Bases (KBs) in the Linked Ope 1 Data (. JD) cloud¹. This has led to the creation of large $\operatorname{orp} c_{a}$, *n* aking billions of RDF² triples available from different Comains such as Geography, Government, Life Sciences. ⁴edia, Publication, Social Networking, and User generated data. The KBs evolve over time: their data instances and sch ... as are updated, extended, revised and refactored [1]. U like in more controlled types of knowledge bases, the evolution KBs exposed in the LOD cloud is usually unrestraine/ [2] which may cause data to suffer from a variety of qualit_iss es, ? both schema level and data instance level. Considering ... ? ¿gregated measure of conformance, the empirical audy carried out by Debattista et al. [2] shows that datasets published in the LOD cloud have reasonable overall quality but indicant issues remain concerning different quality metric. such as data provenance and licensing. Therefore, by looking at individual metrics, we can explore certain aspects, for ...ample data quality issues in the data collection or integral on processes.

Data quality relates c the perception of the "fitness for use" in a given context [3]. One of the common tasks for data quality assessment is to perform a detailed data analysis with data

profiling [4]. Data profiling is usually defined as the process of examining data to collect statistics and provide relevant metadata about the data [5]. Based on the information we gather from data profiling, we can thoroughly examine and understand a KB, its structure, and its properties before using the KB. Various approaches have been developed for KB quality assessment based on manual, semi-automatic, and automated approaches. For example, Flemming's [6] data quality assessment approach evaluate data quality scores based on manual user input for data sources. RDFUnit³ is a tool centered around the definition of integrity constraints for automatic validation tasks. These approaches can ensure an appropriate quality assessment procedure, but it is challenging to continuously and automatically access a evolving KB [7]. Various approaches are based on low-level rules and programs, which require a significant user involvement. Furthermore, in the current literature less focus has been given into studying the evolution of a knowledge base to detect quality issues.

Ellefi *et al.* [8] explored data profiling features of KB evolution by considering the use cases presented by Käfer *et al.* [9]. KB evolution analysis using data profiling features can help to understand the changes applied to an entire KB or parts of it. It has multiple dimensions regarding the dataset update behavior, such as frequency of change, change patterns, change im-

¹http://lod-cloud.net

²https://www.w3.org/RDF

³http://github.com/AKSW/RDFUnit

pacts, and causes of change. More specifically, by exploring KB evolution, we can capture those changes that happen often; or changes that the curator wants to highlight because they are useful or interesting for a specific domain or application; or changes that indicate an abnormal situation or type of evolution [10, 7, 11].

The KB evolution can directly impact the data integration tasks (e.g., matching, linking), that may lead to incomplete or incorrect results [12]. For example, Wikipedia has grown into one of the central hubs of knowledge sources, and it is maintained by thousands of contributors. It evolves each day with contributions from editors all over the world. DBpedia is a crowd-sourced knowledge base and extracts structured information from various Wikipedia projects. This extracted data might have quality problems because either they are mapped incorrectly or the source information itself is incorrect [13].

Considering the level of changes and complexity, KB evolution can be explored based on both simple changes at low-level and complex changes at high-level [7]. Low-level changes are easy to define and have several interesting properties [7]. For example, low-level change detection in its simplest form performs two operations, detection of addition and deletion, which determine individual resources that were added or deleted in a KB [7, 14]. However, a detailed low-level and automated analysis is computationally expensive and might result into a huge number of fine-grained issue notifications [15]. Such amount of information might cause an information overload for the receiver of the notifications. On the contrary, high-level analysis captures the changes that indicate an abnormal situa. on and generates results that are intuitive enough for a human user. However, high-level analysis requires fixed set of requirements (*i.e.*, integrity constraints) to understand underlying chan, es happened in the dataset [7]. A data quality asses. ment pproach using high-level change detection may 1 ad to inc. easing the number of false positive results if the v rsio of a XB is deployed with design issues, such as erroner as sc. pm. definitions [11].

In particular, a knowledge base is defined to be consistent if it does not contain conflicting or contradic ... data [16]. Without proper data management, the dataset in a evolving KB may contain consistency issues [17]. When schema is available with integrity constraints, the date usu lly goes through a validation process that verifies the command against those constraints. Those integrity constraints energy ulate the consistency requirements of data in order to fit fc a set of use cases. Considering the limitations of his h-level hange detection and the changes present at the schma level, integrity constraints based consistency analysis call help to validate the high-level analysis result. Traditionall, in dat bases, constraints are limitations incorporated in the data that are supposed to be satisfied all the time by instances 101. They are useful for users to understand data as they a present characteristics that data naturally exhibits [19]. In pluctical settings, constraints are used for three main tasks: (i) specifying properties that data should hold; (ii) handle contradictions within the data or with respect to the domain under consideration; or (iii) for query optimization. Taking into account ontologies for validation tasks, there

are, however, significant theoretical and practical problems. For example, the OWL W3C Recommendation, based on Description Logic and the Open World A sumption, was designed for inferring new knowledge rather han for validating data using axioms. Reasoners and validators ha, different functions, i.e., a reasoner is used for inferring new knowledge, even though it may find some inconsist ncie as well, while a validator is used for finding violations a_{5} , nst a set of constraints. It is a tedious, time-consuming, a. ¹ error-prone task to generate such validation rules manu 11y. Some of the validation rules can be encoded into the on' log', bu, it still requires a lot of manual effort. This leads to the eed for an approach for inducing such validation rules atomatically. Such rules can be represented in the form of I DF shat 's by profiling the data and using inductive approache to e tract the rules. Other use cases for inducting sha les include describing the data (which is helpful in validating t = (omp) steness analysis results).

In this work, based on the high-level change detection, we aim to analyze completeness issues in any knowledge base. In partice bar, we ddress the challenges of completeness analysis receiving KB using data profiling features. We explore completeness of KB resources using metrics that are computed using KB evolution analysis. The first hypothesis (H1) that has guided our investigation is:

yum profiling features can help to identify completeness isses.

Ve formulate this research goal into the following research question:

RQ1: To what extent the periodic profiling of an evolving KB can contribute to unveil completeness issues?

In response to RQ1, we explore the completeness analysis approaches similar to the work presented in [11]. In particular, we explore multiple data profiling features at the class level and at the property level to define completeness quality measures. For the measurement functions, we use basic summary statistics (i.e. counts and diffs) over entities from periodic KB releases.

To validate the completeness analysis results, we present an experimental analysis that is based on a qualitative and constraints-based validation approach. We propose constraints based feature extraction approach to address the challenges of consistency issues identification in an evolving KB. For constraints-based consistency evaluation, we derived the second hypothesis (H2):

Learning models can be used to predict correct integrity constraints using the outputs of the data profiling as features.

We present this research goal into the following research question:

RQ2: *How can we perform consistency checks using integrity constraints as predictive features of learning models?*

To address RQ2, we use KB data profiling information to generate integrity constraints in the form of SHACL [20] RDF shapes. More specifically, we learn what are the integrity constraints that can be applicable to a large KB by instructing a process of statistical analysis for feature extraction that is followed by a learning model. Furthermore, we performed qualitative analysis to validate the proposed hypothesis by manually examining the results of the completeness analysis. The remainder of this paper is organized as follows:

- In Section 2, we present background and motivational examples that demonstrate important key elements of our quality assessment and validation approach;
- In Section 3, we present the related work focusing on linked data dynamics, knowledge base quality assessment, and knowledge base validation;
- In Section 4, we explore the concept of KB evolution analysis to drive completeness measurement functions and the process of integrity constraints based on shape induction for consistency analysis;
- In Section 5, we present our data driven completeness and consistency analysis approach;
- In Section 6, we present an experimental analysis based on two KBs, namely DBpedia and 3cixty Nice. Furthermore, we considered both English and Spanish versions of DBpedia KB;
- In Section 7, we discuss the hypothesis, the research questions and insights gathered from the experimentation. We also list potential threats emerged while testing the proposed approach;
- In Section 8, we conclude by revisiting each research ques tion and outlining future research endeavours.

2. Background and Motivation

In this work, we explored two KBs namely, the 3cL ty Nice [21] and DBpedia [22]. Here we report a few common prefixes used over the paper:

- DBpedia ontology URL⁴ prefix: *dbo*;
- DBpedia resource URL⁵ prefix: *dbr*
- FOAF Vocabulary Specification UKL prefix: *foaf*;
- Wikipedia URL⁷ prefix: wikipedia-
- 3cixty Nice event type URL⁵ pre².x: *l* de;
- 3cixty Nice place type U^r...[°] pren. dul.

In this section, we present on over liew of the two main research areas: (i) identification of completeness issues using KB evolution analysis, and ii) identification of consistency issues based on integrity construints. Also, we outline the approaches for gold standard creation and tearning models.

2.1. Identification of completeness issues using KB evolution analysis

For a specific context of use, completeness issue is associated with an entity having all z_{n_1} acted attributes [23]. More specifically, it is associated with the q_1 ality issues related to missing entities or missing pro-erties of a knowledge base. This may happen because c_1 an inexpected deletion or because of data source extraction gross.

Fine-grained completenes, analysis based on low-level changes brings subst ntia data processing challenges [7, 12]. More specifically, louvelet el change detection compares the current dataset version with . previous one and returns the delta containing the dded c deleted entities. For example, two DBpedia version 3 - 201 10 and 201604 - have the property dbo:areaTotr' in the Lomain of dbo:Place. Low-level changes can help t det a dded or deleted instances for dbo:Place entity type. In of the main requirements for quality assessment would be to identify the completeness of dbo: Place entity type with thich KB releases. Low-level changes can help only to a tect hissing entities with each KB release. Such as those c. tities missing in the 201604 version (e.g. dbr:A_Rúa, ("______, dbr:Coles_Qurense). Furthermore, these instances are ... 'tomatically extracted from Wikipedia Infobox keys. We mok the Wikipedia page from which DBpedia statements were y racted. These instances are present in the Wikipedia Infc ox as Keys but missing in the DBpedia 201604 release. It . not feasible to manually check all such missing entities or attributes. Thus, because of the large volume of the dataset, it is a tedious, time-consuming, and error-prone task to perform such quality assessment manually.

The representation of changes at low-level leads to syntactic and semantic deltas [14] from which it is more difficult to get insights to complex changes or changes intended by a human user. On the contrary, high-level changes can more efficiently capture the changes that indicate an abnormal situation and generates results that are intuitive enough for a human user. High-level changes from the data can be detected using statistical profiling. For example, total entity count of *dbo:Place* type for two DBpedia versions – 201510 and 201604 – is 1,122,785 and 925,383 where the entity count of 201604 is lower than 201510. This could indicate an imbalance in the data extraction process without fine-grained analysis.

As an example, let us consider a DBpedia ES^{10} entity *dbo:Place/prefijoTelefónicoNombre:Mauricie.*¹¹ When looking at the source Wikipedia page,¹² we observe that, as shown in Figure 1, the infobox reports a "Prefijo telefónico" datum. The DBpedia ontology includes a *dbo:Place/prefijoTelefónicoNombre*, and several other places have that property, but the entity we consider is missing that information.

While it is generally difficult to spot that kind of incompleteness, for the case under consideration it is easier because

¹²https://es.wikipedia.org/wiki/Mauricie

that property was present for the entity under consideration in the previous version of DBpedia ES [22] i.e. the 2016-04 release. It is a completeness issue introduced by the evolution of the knowledge base. It can be spotted by looking at the frequency of predicates inside for an entity type. In particular, in the release of 201610 there are 55, 387 occurrences of the *dbo:Place/prefijoTelefónicoNombre* predicate over 356, 479 *dbo:Place* entity type, while in the previous version (201604) they were 56, 109 out of 657, 481 *dbo:Place* entities.

Figure 1: Example of incomplete Wikipedia data.

Based on the linked data dynamicity behaviour [17, 8, 9], we can assume that the growth of the entities in a mature KB ought to be stable. In this aspect, another complet ness is we relates to entities that were present in the previous prowledge base releases, but disappeared from more recertones. The an example, let us consider a 3cixty Nice entity of type to de Event that has as label: "Modéliser, piloter et valorisent and ifs des collectivités et d'un territoire grâce aux magnettes numériques: retours d'expériences et bonnes pratiques". This entity happened to be part of the 3cixty Nice KB since it has been created the first time, but in a subsequent rel ase i got removed even though it should not. Such a problem is generally complex to be traced manually because it requires a referesource check over the different releases. It can, instand be stotted by looking at the total frequency of entities of a given resource type.

2.2. Identification of consistency issues based on integrity constraints

Another issue of unr strainet KB evolution is the unavailability of explicit schem, inform tion that precisely defines the types of entities and their properties [10]. In a KB, when an ontology is available vith reporties [10]. In a KB, when an ontology is available vith report axioms, which define the conceptualization of the demain, a reasoner can be used to verify whether the dataset is consistent with the domain by verifying the axioms defined in the ontology [24]. The empirical study presented by Mihindukulasooriya *et al.* [13] pointed out that changes in the ontology depend on the development process and the community involved in the creation of the knowledge base.

 $F_{1_{E}} \sim 2$: Example of a 3cixty Nice KB entity that unexpectedly disappeared from the release of 2016-06-15 to the other 2016-09-09.

Th y also pointed out the drawbacks of finding practical guidelines and best practices for ontology based evaluation. Taking into account availability of schema with integrity constraints, the data usually goes through a validation process that verifies the compliance against those constraints. Those integrity constraints encapsulate the consistency requirements of data in order to fit for a set of use cases. For example, in a relational database, the integrity constraints are expressed in a data definition language (DDL), and the database management system (DBMS) ensures that any data inserted into the entire database will not lead to any inconsistency.

The validation of entities in a KB is not done in the same manner as in traditional database management systems due to the lack of a language for expressing constraints or having less restrictive generic models suitable for wider use and not for specific use cases. Furthermore, most of the ontologies do not have rich axioms that could help to detect inconsistencies in data [24]. Further, most of the schema information about RDF data is only available in the form of OWL ontologies that are most suited for entailment rather than validation. In this account, we can assume that practical use cases that utilize RDF data need the validation of integrity constraints. Larger knowledge bases, such as DBpedia, lack the precise definition of integrity constraints, and it is a tedious task to create these constraint definitions from scratch manually. In DBpedia KB [25] (version 2016-04), a person should have exactly one value for the "dbo:birthDate" property or the values of the "dbo:height" property should always be a positive number. The instances of the Person class have more than 13,000 associated properties (including dbo, DBpedia ontology properties and dbp, autogenerated properties from Wikipedia infobox keys). Taking into account ontologies for consistency analysis, they are usually designed for entailment purposes rather than for assessment and their representation often lacks the granular information needed for validating constraints in the data [26]. This leads to the need of automatic consistency analysis for evolving KBs.

2.3. Gold Standard Creation

KBs may contain errors, thus the profiling results cannot be considered as a gold standard. There are different strategies to evaluate a dataset. In the following, we present three common strategies when dealing with a knowledge base [27]:

(*i*) *Silver Standard:* this strategy is based on the assumption that the given KB is already of reasonable quality. The silver standard method is usually applied to measure the performance of knowledge graph by analyzing how well relations in a knowledge graph can be replicated. Although this strategy is suitable for large-scale data, it can produce less reliable results [28, 29].

(ii) Gold standard: this strategy is based on turning the observations in a set of gold data points by human annotators. In this context, gold standard is indeed suitable for our approach since we can obtain gold insights of the completeness measurement results, however it is very expensive if the annotation load is large.

(iii) Partial gold standard: in this strategy, a small subset of external graphs, entities or relations are selected as validation criteria and they, then, are manually labeled [28]. This helps r, ducing the number of candidates that an annotator will process.

2.4. Learning Models

We considered consistency analysis of instances using RDF shape induction as a classification problem. Typic .1ly a c1 ssification learning model maps observations (sample) to a et of possible categories (classes) [30]. For exar ple, the inimum cardinality value of an entity type is an o' serv tion for its relevant attributes (features). For selecting ' sun, 'le ' sarning model for our problem, we investigated the following research question: "Which learning model is the most and mate for consistency analysis using data profiling in an ation as predictive features?". In order to answer this cuestion, we evaluate the performance of predictive features using ve classical learning models. These learning models are cho' en considering five categories of machine learning alg. "ith as [? J]: (i) Neural Networks, (ii) Bayesian, (iii) Instance ь. ч, (iv) Support Vector Machine, and (v) Ensemble. Folloving we present details of those tested in this work.

Multilayer Perceptron ^[24]: a forward Neural Network consisting of at least these layer of neurons with a non-linear activation function: one for inputs, one for outputs and one or more hidden layers. Training is carried out through back propagation.

Naive Bayes [32]: 1. a simple probabilistic classifier. The core concept is based on the Bayes theorem [32]. Generally, naive bayes classifiers are based on the assumption that features are independent with each other.

k-Nearest Neighbors (k-NN) [33]: is an instance-based learning algorithm. It locates the *k*-nearest instances to the input instance and determines its class by identifying the single most frequent class label. It is generally considered not tolerant to noise and missing values. Nevertheless, it is highly accurate, insensitive to outliers and work well with both nominal and numerical features.

Support Vector Machines (5 'M) [34]: it conceptually implements the following id a: *i* put vectors are non-linearly mapped to a very high dimensional feature space. In this feature space a linear decision survey is constructed. Special properties of the decision survey ensures high generalization ability of the classifier.

Random Forest [35]: creates many classification trees. To classify a new coject from an input vector, it maps the input vector down each of the rees in the forest. Each tree gives a classification and the ay the tree "votes" for that class. The forest choo es the classification having the most votes (over all the trees in 'r rores').

In our n. deling phase, we applied a k-fold cross validation [30] to reduce the variance of a performance score. In the k-fold cross validation, setup, k is the number of splits to make in the datase. We choose value of k=10. This results in splitting the dataset. We choose value of k=10. This results in splitting the dataset. The portions (10 folds) and runs the learning model 10 times. For each algorithm, the training runs on 90% of the data and testing on the left 10%. With k value of 10, it uses ea n data instance as a training instance exactly 9 times and test instance 1 time.

We also adopted general classification performance evaluation measures such as precision, recall, and F1 score [36]. Evaluation of the classification performance is based on considering one of the output classes as the positive class and defining: *(i)* true positives (TP): the number of samples correctly labeled as in the positive class; *(ii)* false positives (FP): the number of samples incorrectly labeled as in the positive class; *(iii)* true negatives (TN): the number of samples correctly labeled as not in the positive class; *(iv)* false negatives (FN): the number of samples incorrectly labeled as not in the positive class.

We present the formulas of the aforementioned metrics:

- **Precision** (*P*): it is based on positive predictive value and it defined as $P = \frac{TP}{TP+FP}$;
- **Recall** (*R*): it is related to true positive rate also know as sensitivity and it is defined as $R = \frac{TP}{TP+FN}$;
- **F1 Score** (*F*1): it is a measure of test accuracy and it is defined as the harmonic mean of precision and recall: $F1 = \frac{2*P*R}{P+R}$.

3. Related Work

This section provides an overview of the state-of-the-art in the context of knowledge base quality assessment approaches. The research activities related to our approach fall into three main areas: (*i*) Linked Data Dynamics, (*ii*) Knowledge Base Quality Assessment, and (*iii*) Knowledge Base Validation.

3.1. Linked Data Dynamics

Taking into account changes over time, every dataset can be dynamic. Considering linked data dynamics, a comparative analysis is present by Umbrich *et al.* [37]. The authors analyzed entity dynamics using a labeled directed graph based on LOD, where a node is an entity that is represented by a subject. In addition, Umbrich *et al.* [38] presented a comprehensive survey based on technical solutions for dealing with changes in datasets of the Web of Data. Furthermore, Käfer *et al.* [9] designed a Linked Data Observatory to monitor linked data dynamics. The authors setup a long-term experiment to monitor the two-hop neighborhood of a core set of eighty thousand diverse Linked Data documents on a weekly basis. Furthermore, linked data dynamics is considered using five use cases: synchronization, smart caching, hybrid architectures, external-link maintenance, and vocabulary evolution and versioning.

The work presented by Papavasileiou et al. [7] explored highlevel change detection in RDF(S) KBs by addressing change management for RDF(S). The authors explored the data management issues in KBs where data is maintained by large communities, such as scientists or librarians, who act as curators to ensure high quality of data. Such curated KBs are constantly evolving for various reasons, such as the inclusion of new experimental evidence or observations, or the correction of erroneous conceptualizations. Managing such changes poses several research problems, including the problem of detecting the changes (delta) among versions of the same KB developed. and maintained by different groups of curators, a crucial task for assisting them in understanding the involved changes. The authors addressed this problem by proposing a language for change detection that allows the formulation of corine and intuitive deltas. Similarly, in our work, we explor the del as present in consecutive KB releases using data profilm.

analysis of the ontologies that were develope col'abor lively to understand community-driven ontology volu. n/n practice. The authors have analyzed, how four cell-known ontologies (DBpedia, Schema.org, PROV-O, and FOA), have evolved through their lifetime and they observed quality issues were due to the ontology evolution. Also, t¹ e au¹ fors pointed out the need for having multiple methodologies . " managing changes. The authors summarize that the sf ecte 1 ontologies do not follow the theoretical frameworks found in the literature. Further, the most common quality problems cau . by ontology changes include the use of abandonec classes and properties in data instances and the presence of ⁴uplicat classes and properties. Nevertheless, this work is not not seed on KB evolution analysis for completeness ; halysis ut rather on how changes in the ontology affect the tota des ribed using those ontologies. Klein et al. [39] studied the ontology versioning in the context of the Web. The au hor nocked at the characteristics of the release relation betwee, ontologies and at the identification of online ontologies. Then, a web-based system is introduced to help users to manage changes in ontologies. Similarly, Pernelle et al. [12] presented an approach that detects and semantically represents data changes in knowledge bases. However, ontologies description for KBs are not always available [13]. In this

work, we focus on KB evolution analysis using data profiling at the data instance level to address the issues concerning unavailability of ontology descriptions.

In [10], Nishioka *et al.* preserved a clustering technique over the dynamics of entities to de ermine common temporal patterns. The quality of the cluber ring is evaluated using entity features such as the entitie z_1 properties, RDF types, and paylevel domain. Besides, the autions investigated to what extent entities that share a feature rolue change over time. In this paper, we explore linked zy_1 unic data features for detecting completeness issues. In read of using a clustering technique [10] based on the temporary of entities, we focus on exploring the evolution analysis as a classification problem to detect completeness is ues.

3.2. Knowl age Pase Quality Assessment

Knowled re Lase juality assessment is a largely investigated research field, and many approaches to data quality management have been proposed. There exists a large number of data quality framew rks and tools based on manual, crowd-sourced, and a tomatic approaches. In this section, we review literature that analy. The quality of various aspects of KBs.

Comprehensive Studies. A comprehensive overview of the RDF a. a profiling is presented by Ellefi *et al.* [8]. The authors explored the RDF data profiling feature, methods, tools, and cabularies. Furthermore, the authors presented dataset profiling in a taxonomy and illustrated the links between the dataset profiling and feature extraction approaches. Ellefi *et al.* organized dataset profiling features into seven top-level categories: 1. General; 2. Qualitative; 3. Provenance; 4. Links; 5. Licensing; 6. Statistical; 7. Dynamics. The authors considered linked data dynamics as profiling features using the study presented by Käfer *et al.* [9]. Similarly, in this work, we explore the concepts regarding qualitative, statistical, and dynamic features. Also, based on Ellefi *et al.* [8] study, we explore the dynamic features to perform completeness analysis.

Considering the data quality methodologies applied to linked open data (LOD), a comprehensive systematic literature review is presented by Zaveri et al. [40]. The authors have extracted 26 quality dimensions and a total of 110 objective and subjective quality indicators. Zaveri et al. organized the linked data quality dimensions into the following categories, 1. Contextual dimensions; 2. Trust dimensions; 3. Intrinsic dimensions; 4. Accessibility dimensions; 5. Representational dimensions; 6. Dataset dynamicity dimensions. Furthermore, dataset dynamicity dimensions are explored using three quality dimensions: 1. Currency: speed of information update regarding information changes; 2. Volatility: length of time which the data remains valid; 3. Timeliness: information is available in time to be useful. The work presented in this paper is related to contextual and dataset dynamicity dimensions. More concretely, the completeness and consistency is associated with the contextual dimensions, and the dataset evolution is related to the dataset dynamicity dimensions.

Quality Assessment Frameworks. Taking into account data quality analysis using manual approaches, Bizer *et al.* [41] presented Web Information Quality Assessment Framework (WIQA). The WIQA - Information Quality Assessment Framework is a set of software components that empowers information consumers to employ a wide range of different information quality assessment policies to filter information from the Web. This framework employs the Named Graphs data model for the representation of information together with quality-related meta-information and uses the WIQA-PL¹³ policy language for expressing information filtering policies. WIQA-PL policies are expressed in the form of graph patterns and filter conditions. WIQA can be used to understand the intended changes present in a KB by applying graph patterns and filtering conditions. In this work, instead of a static version of a KB, we plan to explore multiple versions of KB using WIQA policy.

Using provenance metadata information, Mendes *et al.* [42] presented Sieve framework that uses user configurable quality specification for quality assessment and fusion method. Sieve is integrated as a component of the Linked Data Integration Framework (LDIF).¹⁴ In particular, Sieve uses the LDIF provenance metadata and the user configured quality metrics to generate quality assessment scores. A set of Linked Data quality assessment measures are proposed as: 1. Intensional completeness; 2. Extensional completeness; 3. Recency and reputation; 4. Time since data modification; 5. Property completeness; 6. Property conciseness; 7. Property consistency. In this work, instead of using provenance metadata and the user configured quality metrics, we explore completeness using dynamic linked data profiling features presented by Ellefi *et al.* [8].

In [43], Kontokostas et al. proposed a methodology for testdriven quality assessment of Linked Data. The authors for, nized quality issues and employed SPARQL query templates, which are instantiated into quality test queries. Also the authors presented RDFUnit¹⁵ a tool centered around schema vilidation using test-driven quality assessment approac. RDF Jnit runs automatically based on a schema and manually generates test cases against an endpoint. RDFUnit ' as a com' onent that turns RDFS axioms and simple OWL axi ms in 5 ARQL queries that check for data that does not r the axiom. In contrast, in this study, we aim to learn the condraints (which might not be explicitly stated as RDFS c UL axioms) as RDF Shapes. Although the overall objectiv s are similar considering RDF shape induction to this work, for completeness analysis we mainly explore KB evolution *r* haly is. Furthermore, in our approach, we primarily use data pofiling ir formation as the input for the process. Results from the visitency analysis can be extended by using RDFU1 it for ft. ther validation.

In [15], Debattista *et al.* propented *e* conceptual methodology for assessing Linked Data Caality A proposed Luzzu, a framework for Linked Data Caality A proposed Luzzu is based on four major components. 1. An axtensible interface for defining new quality metrics; 2. An interoperable, ontology-driven back-end for representing quality metadata and quality problems that can be re-used within different semantic frameworks; 3. Scalable dataset processors for data dumps, SPARQL end-

points, and big data infrastructures; 4. A customisable ranking algorithm taking into account user-defined weights. Luzzu is a stream-oriented quality assessment framework that focuses on data instance-centric measure nent of a user-defined collection of quality metrics. The alidad in metrics require users to write Java code for impler ... ting checks. In this work, we perform completeness anal sis h sed on high-level change detection to identify any proble. In the data processing pipeline. Furthermore, various resea. h works explored the importance of quality metrics in $\tau \rho_1$ babin, tic and deterministic settings. Debattista et al. [44' expl reu probabilistic techniques such as Reservoir Sampling, D. om Filters and Clustering Coefficient estimation for in plementing a broad set of data quality metrics in an approxim te but s fficiently accurate way. In addition, various research corks put emphasis on the problem of error detection ir a KP For example, distance-based outlier detection by Devatt sta et al. [45] and error detection in relation assertions ("Melo al. [46] gave more focus towards error detection in schemas. The core of the study is similar considering error tection in a KB, the focus of this study is to identify com₁⁻¹-tene... and consistency issues using various data profiling featur.

Trowdsourcing. A crowd-sourcing quality assessment approach can be used to understand the intended changes by sta .enolders due to KB updates. Acosta et al. [47] introduced a prowd-sourcing quality assessment approach that is difficult to uncover quality issues automatically. The authors explored most common quality issues in DBpedia datasets, such as incorrect object values, incorrect datatype or language tag and incorrect link. The authors introduced a methodology to adjust crowdsourcing input from two types of audience: (i) Linked Data experts through a contest to detect and classify erroneous RDF triples and (ii) Crowdsourcing through the Amazon Mechanical Turk. In detail, the authors adapted the Find-Fix-Verify crowdsourcing pattern to exploit the strengths of experts and paid workers. Furthermore, the authors used TripleCheck-Mate [48] a crowdsourcing tool for the evaluation of a large number of individual resources, according to a defined quality problem taxonomy. To understand the quality of data sources, Flemming's [6] presented an assessment tool that calculates data quality scores based on manual user input for data sources. More specifically, a user needs to answer a series of questions regarding the dataset and assigns weights to the predefined quality metrics. However, it lacks several quality dimensions such as completeness or inconsistency. In [43], Kontokostas et al. proposed a methodology for test-driven quality assessment of Linked Data. The authors formalized quality issues and employed SPARQL query templates, which are instantiated into quality test queries. Also, the authors presented RDFUnit¹⁶ a tool centered around schema validation using test-driven quality assessment approach. RDFUnit runs automatically based on a schema and manually generates test cases against an endpoint. RDFUnit has a component that turns RDFS axioms and simple OWL axioms into SPARQL queries that check for data

¹⁶https://github.com/AKSW/RDFUnit

that does not match the axiom. In contrast, in this study, we aim to learn the constraints (which might not be explicitly stated as RDFS or OWL axioms) as RDF Shapes. Although the overall objectives are similar considering RDF shape induction to this work, for completeness analysis we mainly explore KB evolution analysis. Furthermore, in our approach, we primarily use data profiling information as the input for the process. Results from the consistency analysis can be extended by using RDFUnit for further validation.

Metadata. In [49], Assaf *et al.* introduced a framework that handles issues related to incomplete and inconsistent metadata quality. The authors proposed a scalable automatic approach for extracting, validating, correcting and generating descriptive linked dataset profiles. This framework applies several techniques to check the validity of the metadata provided and to generate descriptive and statistical information for a particular dataset or an entire data portal. In particular, the authors extensively used dataset metadata against an aggregated standard set of information. This procedure leads to dependency towards availability of metadata information. Instead, in our approach, we only focus on summary statistics from the collected dataset, and it is independent of external information since the quality profiling can be done only using summary statistics.

Temporal Analysis. In [50], Rula *et al.* started from the premise of dynamicity of Linked Data and focused on the assessment of timeliness in order to reduce errors related to outdated data. A currency metric is introduced to measure timeliness, that is calculated in terms of differences between the observation is done (current time) and the time when the data as modified for the last time. Furthermore, authors also took into account the difference between the time of data observation and the time of data creation. Similarly, in our work, we explore and the time of data creation. Similarly, in our work, we explore a timeless measures, we investigate the changed by navior present in the dataset using dynamic profiling features into duried by Ellefi *et al.* [8].

In [51], Furber and Hepp focused on the assessment of accuracy, which includes both syntactic and semilatic accuracy, timeliness, completeness, and uniqueness. One measure of accuracy consists of determining inaccurate values using functional dependence rules, while timeliness is measured with time validity intervals of instances and their expiry dates. Completeness deals with the assessment 6. the completeness of schema (representation of ontology elements), the properties (represented by mandato groups ty and literal value rules), and completeness of population (description of real-world entities). Uniqueness refers the accuracy and it referses the changes present in the KB to identify completeness issues.

Considering the version management and linked data lifecycle, Knuth *et al.* 52] .acritified the critical challenges for Linked Data quality. A. one of the key factors for Linked Data quality they outlined valication that, in their opinion, has to be an integral part of Linked Data lifecycle. An additional factor for Linked Data quality is version management, which can create problems in provenance and tracking. Finally, as another essential factor they outlined the usage of popular vocabularies or manual creation of new correct vocabularies. Furthermore, Emburi *et al.* [53] developed a framework for automatic crawling the Linked Data datasets and improving dataset quality. In their work, the quality is focused on corrors in data, and the purpose of the developed framework is to automatically correct errors.

Statistical analysis. Pau'. 'm et al. [54] presented two approaches SDType and SDVa' date for quality assessment. SDType approach help to p. fict RDF resources type thus completing missing values f rdt. ype properties. SDValidate approach detects incrine t link, between resources within a dataset. These meth ds c in effectively detect errors on DBpedia; however they requ. • the existence of informative type assertions. Further nore, more complex errors containing wrong entities with cc rect typ s cannot be identified. Taking into account, the prot. bilist's approach for linked data quality assessment, I et al [55] presented a probabilistic framework using the rela 'or', (eq. al, greater than, less than) among multiple RDF predicates to letect inconsistencies in numerical and date values based the statistical distribution of predicates and objects n. RDF d: asets. However, they mainly focused on identifying error in the numerical data. In [56], Ruckhaus et al. presentea 'iQuate, a tool based on probabilistic models to ana, re the quality of data and links. The authors used Bayesian Networ's and rule-based system for quality assessment. The pre sacilistic rules are represented by data experts to identify rendant, incomplete and inconsistent links in a set of resources. In our approach, we mainly focus on statistical profiling at the instance level. This reduces the dependency on expert interven-.ion.

In the current state of the art, less focus has been given toward understanding knowledge base resource changes over time to detect anomalies and completeness issues due to the KB evolution. For an evolving KB, we investigated two perspectives: (*i*) Static: data quality analysis with respect to specific tasks without considering dataset dynamics; (*ii*) Dynamic: process of accessing data and temporal analysis, such as timeliness measure. In Table 1, we summarize the reported linked data quality assessment approaches.

3.3. Knowledge Base Validation

The problem of knowledge base validation has been explored using *Description Logics* considering both Open World (OW) and Closed World (CW) Assumption. In recent years, various validation languages have been introduced using constraint definitions.

• The Web Ontology Language (OWL) [57] is an expressive ontology language based on Description Logics (DL). The semantics of OWL addresses distributed knowledge representation scenarios where complete knowledge about the domain cannot be assumed. Motik *et al.* [58] proposed an extension of OWL that attempts to mimic the intuition behind integrity constraints in relational databases. The authors divided axioms into regular and constraints. To address the problem of validation using OWL representation, some approaches use OWL expressions with Closed World Assumption and a weak Unique Name Assumption

 Table 1: Summary of Linked Data Quality Assessment Approacies.

so that OWL expressions can be used for validation purposes, such as the work presented by Tao *et al.* [59], and Stardog ICV¹⁷.

- The Shape Expressions (ShEx) [60] language describes RDF nodes and graph structures. A node constraint describes an RDF node (IRI, blank node or literal) and a shape describes the triples involving nodes in an RDF graph. These descriptions identify predicates and their associated cardinalities and datatypes.
- The W3C Shapes Constraint Language (SHACL) [20] is used for validating RDF graphs against a set of conditions. These conditions are provided as shapes and other constructs expressed in the form of an RDF graph. In particular, it helps to identify constraints using SPARQL. Also, it provides a high level vocabulary to identify predicates and their associated cardinalities, and datatypes. SHACL is divided into two parts: (i) SHACL Core, describes a core RDF vocabulary to define common shapes and constraints; and (ii) extension mechanism named SHACL-SPARQL. In this work, we explore the SHACL Core for consistency evaluation. We look at SHACL Shape for a specific class to identify constraints components. In SHACL, a Shape is defined as the collection of targets and constraints components. Targets specify which nodes in the data graph must conform to a shape and constraint components determine how to validate a node. Shapes graph represent an RDE graph that contains shapes. Conversely, Data graph represents an RDF graph that contains data to be validated. thermore, SHACL defines two types of Shapes: (i) Node shapes presents the constraints information abover viven focus node; and (ii) Property shapes present constraits about a property and values of a path for a node.
- SPARQL Inference Notation (SPIN)¹⁸ constraints associate RDF types or nodes with validation west on particular, it allows users to use SPARQL o specify alles and logical constraints.

These shape expression languages, ' and ly, ShEx, SHACL, and SPIN, aim to validate RDF data nd t communicate data semantics among users. They cov r con traints such as keys and cardinality; however, their e pres ivity is limited and require user interventions in even, sep. Furthermore, various research endeavors explored the $\kappa_{\rm c}^{\rm opt}$ validation based on the Closed World Assumpt on (CV, A). For example, Patel-Schneider [61] explored Description Logics as a mean to provide the necessary framer ...k for mecking constraints and providing facilities to anal ze CWr 3. The authors utilized inference as a mean for cons. nint checking, which is the core service provided by Depaription Logics. Our final goal is different from these research . yp Jacnes. In particular, we study how data profiling can be at plied to constraints based feature extraction in a predictive setting. For example, cardinality estimation has been studied in many different domains including

relational data. In addition, integrity constraints for validation tasks has many other applications, such as network monitoring for detecting DDoS attacks or worm propagation, link based spam detection, and relation join viery optimization. The existing cardinality estimation algor thms ... ch as Hit Counting [62], Adaptive Sampling [63], Prc', "ilistic Counting [64] and HY-PERLOGLOG [65] aim to .stim .te the number of distinct elements in very large datasets , h duplicate elements. For cardinality estimation in RDr ¹9ta, Lieuman and Moerkotte [66] have proposed "chara ... stic sc.s" for performing cardinality estimations using SFARC - queries with multiple joins. Overall, these works differ ... m the work presented in this paper on two axes. First, ' ey are focused on determining the cardinalities of each value rather han the cardinality of the entity-value relation. Second, Severa focused on query optimization rather than integri y constraint validation. We consider the profiling of instance. as a me in to estimate constraint values which can help to u. derstand consistency issues.

4. Con, 'eter .ss and Consistency Analysis

In this action, we investigate the concept of KB evolutic. analysis to derive completeness measurement functions. For condistency analysis, we explore integrity constraints using ships induction for feature extraction.

4.1. Evolution Analysis and Dynamic Features

Large KBs are often maintained by communities that act as curators to ensure their quality [67]. The benefit of KB evolution analysis is two-fold [17]: (1) quality control and maintenance; and (2) data exploitation. Considering quality control and maintenance, KB evolution can help to identify common issues such as broken links or URI changes that create inconsistencies in the dataset. On the contrary, data exploitation can provide valuable insights regarding dynamics of the data, domains, and the communities that explore operational aspects of evolution analysis [17]. KBs naturally evolve due to several causes: (*i*) resource representations and links that are created, updated, and removed; (*ii*) the entire graph can change or disappear. The kind of evolution that a KB is subjected to depends on several factors, such as:

- *Frequency of update:* KBs can be updated almost continuously (e.g. daily or weekly) or at long intervals (e.g. yearly);
- *Domain area:* depending on the specific domain, updates can be minor or substantial. For instance, social data is likely to experience wide fluctuations than encyclopedic data, which is likely to undergo smaller knowledge increments;
- *Data acquisition:* the process used to acquire the data to be stored in a KB and the characteristics of the sources may influence the evolution. For example, updates on individual resources cause minor changes when compared to a complete reorganization of a data source infrastructure such as a change of the domain name;

¹⁷https://www.stardog.com/docs/

¹⁸http://spinrdf.org

• *Link between data sources:* when multiple sources are used for building a KB, the alignment and compatibility of such sources affect the overall KB evolution. The differences of KBs have been proved to play a crucial role in various curation tasks such as the synchronization of autonomously developed KB versions, or the visualization of the evolution history of a KB [7] for more user-friendly change management.

Ellefi *et al.* [8] presented a set of dynamic features for data profiling. In this work, we explore these dynamic features for measuring the completeness quality characteristics. Based on Ellefi *et al.* [8], we explored the following dynamic features:

- *Lifespan*: knowledge bases contain information about different real-world objects or concepts commonly referred as entities. Lifespan represents the period when a certain entity is available and it measures the change patterns of a knowledge base. Change patterns help to understand the existence and the categories of updates or change behavior.
- *Degree of change:* it helps to understand to what extent the performed update impacts the overall state of the knowledge base. Furthermore, the degree of changes helps to understand what are the causes for change triggers as well as the propagation effects.
- Update history: it contains basic measurement elements regarding the knowledge base update behavior such a final quency of change. The frequency of change measures the update frequency of KB resources. For example, the instance count of an entity type for various version as.

4.2. Completeness Analysis based on Dynamic ' eatures

The ISO/IEC 25012 standard [23] refers to complete less as the degree to which subject data associated with an artity has values for all expected attributes and related contributions in a specific context of use. In this paper, for completeness characteristics, we look into the dynamic reative using periodic data profiling in order to identify quality is uses. Taking into account linked data dynamics,¹⁹ the update constrained to the avoid of classes and properties can be stable/growith or unstable [17]. Table 2 illustrates two common types of charge both haviour using property frequency as measurement.

Table 2: Categorie.	of chap	,e	behaviour
---------------------	---------	----	-----------

Туре	vescription
Stable/Growth = 1	If u_{n-1} perty frequency at release N u_{n-1} or greater than $N - 1$
Unstable = 0	the property frequency at release N le.; than $N - 1$

¹⁹https://www.w3.org/wiki/DatasetDynamics

4.2.1. Measurement Elements

Statistical operations using data profiling provides descriptive information about data types and patterns in the dataset. For example, property distributions, number of entities, and number of predicates. For computing the change detection, we used basic statistical operations. We thereby use the following key statistics: (*i*) number of distinct predicates; (*ii*) number of distinct subjects; (*iii*) number of distinct entities per class; (*iv*) frequency of predicates per soft.

In particular, we air i to detect variations of two basic statistical measures that i in b' evaluated with the most simple and computationally inexperience, sive operation, i.e., counting.

The computation is performed on the basis of the classes in a KB release of V i.e. given a class C we consider all entities E of the type C as:

$$\operatorname{Junt}(\ell) = |\{s : \exists \langle s, \text{typeof}, C \rangle \in V\}|$$

The count (C) measurement can be performed with a SPAR OL query such as:

SELEC COUNT (DISTINCT	?s) AS ?COUNT
WHERE { ?s a <c> . }</c>	

The second measure element focuses on the frequency of the preserves, within a class C. We define the frequency of a propy (in the scope of class C) as:

$$freq(p, C) = |\{\langle s, p, o \rangle : \exists \langle s, p, o \rangle \land \langle s, typeof, C \rangle \in V\}|$$

The freq(p, C) measurement can be performed with a SPARQL query having the following structure:

SELECT COUNT(*)	AS	?FREQ
WHERE {		
?s ?o.		
?s a <c>.</c>		
1		

There is an additional basic measure element that can be used to build derived measures: the number of properties present for the entity type C in the release i of the KB. Therefore, distinct property count of entity type C as:

$$NP(C) = |\{p : \exists \langle s, p, o \rangle \land \langle s, \text{typeof}, C \rangle \in V\}|$$

The NP(C) measure can be collected with a SPARQL query having the following structure:

SELECT COUNT(DISTINCT ?p) AS ?NP	
WHERE {	İ
?s ?p ?o.	İ
?s a <c>.</c>	
}	İ

The essence of the proposed approach is the comparison of the measure across distinct releases of a KB. In the remainder, we will use a subscript to indicate the release that the measure refers to. The releases are numbered progressively as integers starting from one and, by convention, the most recent release is *n*. So that, for instance, $count_{n-1}(foaf:Person)$ represents the

count of resources typed with *foaf:Person* in the last but one release of the knowledge base under consideration. More specifically we used the property frequency for a specific class for completeness metrics.

4.2.2. Measurement Functions

On the basis of the dynamic features [8], a further conjecture drive that the growth of knowledge in a mature KB ought to be stable. Furthermore, we argue that completeness issues can be identified through monitoring lifespan of an RDF KBs. A simple interpretation of the stability of a KB is monitoring the dynamics of knowledge base changes [11]. This measure could be useful to understand high-level changes by analyzing KB growth patterns.

We can monitor growth level of KB resources (instances) by measuring changes presented in different releases. In particular, knowledge base growth can be measured by detecting the changes over KB releases utilizing trend analysis such as the use of simple linear regression. Based on the comparison between observed and predicted values, we can detect the trend in the KB resources, thus detecting anomalies over KB releases if the resources have a downward trend over the releases.

We derive KB lifespan analysis regarding change patterns over time. To measure the KB growth, we applied linear regression analysis of entity counts over KB releases. In the regression analysis, we checked the latest release to measure the normalized distance between an actual and a predicted value. In particular, in the linear regression we used entity count (v_i) as dependent variable and time period (t_i) as independent variac '-Here, n = total number of KB releases and i = 1...n present as the time period.

We start with a linear regression fitting the count measure of the class (C):

$$y(C) = a \cdot t + b$$

The residual can be defined as:

$$residual_i(C) = a \cdot t_i + b - c \epsilon \ln(C)$$

We define the normalized distance a :

$$ND(C) = \frac{residval_n(\mathcal{T})}{mean(|r|sidval_i(C)|)}$$

Based on the normalized distance, $\neg c$ in classify the growth of a class C as:

$$Growth(C) = \begin{cases} 1 & if(? D(C)) \ge 1\\ 0 & if(ND(C)) < 1 \end{cases}$$

The value is 1 if the normal zed distance between actual value is higher than the predicted value of type C, otherwise it is 0. In particular, if the F is growth prediction has the value of 1 then the KB may have an unexpected growth with unwanted entities otherwise the KB remains stable.

To further validate our assumptions, we explore the completeness of properties by monitoring the variations due to KB updates. More specifically, by property completeness analysis we focus on the removal of information as an adverse effect of the KB evolution. We can use the frequency of predicates of an entity type as the essential measurement element. Furthermore, by comparing property frequency between two KB releases, we can detect complet pess issues. Considering the changed behavior presented ir. Table 2, the value of 0 means that a property presents in the last release might have completeness issues.

The basic measure we use the frequency of predicates, in particular, since the variated in the number of subjects can affect the frequency, we menduce a normalized frequency as:

$$NF_{i\backslash_{t}}$$
 $C) = \frac{freq_{i}(p, C)}{count_{i}(C)}$

On the basis C^{c} this derived measure we can thus define completeness of a property in the scope of a class C as:

$$Comp_{i, \text{``oness}_{i}}(p, C) = \begin{cases} 1, & \operatorname{NF}_{i}(p, C) \ge \operatorname{NF}_{i-1}(p, C) \\ 0, & \operatorname{NF}_{i}(p, C) < \operatorname{NF}_{i-1}(p, C) \end{cases}$$

where $N_{i}(c)$ is the number of properties present for class C in the reacted in the knowledge base.

At the class level the completeness is the proportion of complete p. Adicates and can be computed as:

$$Completeness_i(C) = \frac{\sum_{k=1}^{NP_i(C)} Completeness_i(p_k, C)}{NP_i(C)}$$

4.3. Consistency Analysis based on Integrity Constraints

Consistency checks whether inconsistent facts are included in the KB [40]. For accessing consistency, we can use an inference engine or a reasoner, which supports the expressivity of the underlying knowledge representation formalism. In the context of KB validation, languages, such as W3C Shapes Constraint Language (SHACL) and Shape Expressions Language (ShEx), allow integrity constraints to be defined for validation tasks. In this work, we explore the integrity constraints definitions present in SHACL core for consistency evaluation. We generate shapes at the class-level using data profiling information. We consider three constraints for consistency checks for evolving KBs: cardinality, range, and string constraint. We consider these three constraints based on the following conditions: (i) to evaluate properties with correct specifications, we explore cardinality constraints to identify the correct mapping of properties for a specific class, and (ii) to evaluate contradictions within the data, we explore the range constraint values.

Taking into account profiling based shape induction tasks, we compute the RDF term at instance-level using the data instances only. We thereby use the following key statistics: (*i*) percentage (%) of IRIs, blank nodes, and literals; (*ii*) no. of triples with IRI and its frequency, length, namespace, patterns; (*iii*) no. of triples with Literals (String/Numeric/Dates) and its frequency, language, length, patterns, min, max, mean, std, variance.

The motivation for using these key statistics is that these statistics could provide some insights related to different possible distributions to identify feature vectors. The percentage

1

(%) of IRIs, blank nodes, and literals are used to extract Range constraints. Also, no. of triples with IRI and its frequency, length, namespace, patterns is used for Range contraints feature extraction. For cardinality and string constraints feature extraction, we considered the triples with literals (String/Numeric/Date) and its frequency, language, length, patterns, min, max, mean, std, variance. For example, based on the raw cardinality value distributions, we can compute the distinct cardinality values. Overall, we derive 11 statistical measures including min-max cardinalities, mean, mode, standard deviation, variance, quadratic mean, skewness, percentiles, and kurtosis [68]. Our intuition is that these values are descriptive to classify the constraints category. Nevertheless, the data can be noisy, and either min or/and max could be outliers. To address this, we add statistical features that give more insights about the distribution of the cardinalities such as mean, mode, kurtosis, standard deviation, skewness, variance and four percentiles.

In the remainder of this section, we describe cardinality, range, and string constraints for feature extraction process. We describe each constraint with examples based on the English DBpedia 201604 release.

Cardinality constraints. We observe a trend in vocabularies where the cardinality constraints are explicitly expressed [69]. When, we analyzed the 551 vocabularies in the *Linked Open Vocabularies (LOV)* catalogue for the values of owl:minCardinality, 96.91% (848 out of 875) o owl:maxCardinality constraints have value 1 and 93.76% (631 out of 673) of the owl:minCardinality values a. Set ther 0 or 1 [69]. Thus, in this work, we explore which cardinality category each property has with respect to a given class. By doing so, we present cardinalit/ value setimation as a classification problem. Table or hows the common cardinality patterns.

For the classification task, we use the fit m in types of cardinality classes: MIN0, MIN1, MU 11+, Λ^A , 1, and MAX1+. Out of these, MIN0 and Λ^A X1+ do not put any constraints on the data, such that, any data will be valid for those cardinality types. Thus, if we detect those types, we do not generate constraints. For other types, corresponding SHACL property constraints are generated as illustrated in Listing 1.

Listing 1:	Cardinalny.	70	raints
------------	-------------	----	--------

Table 3: Minimum an	maλ	mum cardinality lev	els.

Key	Poscrip in
MIN0	$1 \text{ finite} \cap \text{Cardinality} = 0$
MIN1	' rinimum Cardinality = 1
MIN ¹ ±	. "inimum Cardinality >1
M AX1	Aaximum Cardinality = 1
MA. 1+	Maximum Cardinality >1

We generate c'rdinality information for each property associate.' with the instances of a given class. The work precented by Jeumann and Guido [66] helps to identify raw card, ality values using SPARQL queries. They proposed a highly accurate cardinality estimation method for RDF data using star joins SPARQL queries. Similarly, we also corplore the process of cardinality values estimation using the results from SPARQL queries. Thus, our cardinality constraints generation process is based on the study presented by Neumann and Guido [66]. We collected distinct cardinality values by using star join SPARQL query. An example of join SPARQL queries for raw cardinality values estimation is presented in Listing 2.

Listing 2: SPARQL query for the cardinality value estimation.

```
SELECT ?card (COUNT (?s) as ?count )
WHERE {
   SELECT ?s (COUNT (?o) as ?card)
   WHERE {
        ?s a ?class ;
        ?p ?o
        } GROUP BY ?s
} GROUP BY ?card ORDER BY DESC(?count)
```

Range constraints. We use the subset of the target Node already identified in SHACL, i.e., *IRI*, *Literal*, *BlankNode*, and *BlankNodeOrIRI*. Table 4 illustrates the target Node objects type in SHACL. Each value of target Node in shape is either an IRI or a literal. For range constraints, our goals are twofold. First, we want to generate an object as target node constraint for each property associated with a given class. Once the target node type is determined, then more specific range constraints have to be decided. If the node type is *Literal*, the corresponding datatype has to be determined. If the node type is either *IRI*, *BlankNode*, or *BlankNodeOrIRI* the class type of the objects has to be determined.

We classify each property associated with instances of a given class to one of the aforementioned node types. The second task of assigning the corresponding datatype or class as the range of each property is done based on

IRI	BlankNode	Literal	Туре
Х	Х	Х	Any
Х	Х		BlankNodeOrIRI
Х			IRI
	Х		BlankNode
		Х	Literal
Х		Х	IRIOrLiteral
	Х	Х	BlankNodeOrLiteral

Table 4: Objects Type.

heuristics of datatype or class type distributions among the set of objects associated with the property. For example, *dbo:Web* has distribution of 73.13% for IRI node type and 26.89% for LIT node type for *dbo:SoprtsTeam* entity type. In this account, IRI has larger distribution then LIT node type. Based on our heuristics, we considered *dbo:Web* node type as IRI. An example of *dbo:Persondbp:birthPlace* objects nodeKind constraints Shape is illustrated in the Listing 3.

```

String based Constraints. For string based constraints generation the primary form is to understand minimum length (minLength) and maximum, 'ength (maxLength) of a property. In this context max and min length subjected to rdf:type and node with meral values. In general, if the value of minLe. gtb is 0, then there is no restriction on the string length, out the constraint is still violated if the value node is a blank node. On the other hand, the value of maxLength without restriction could be any string length based on the rdf:type. We considered the distribution of string lengths to identify minLength and maxLength of literal values of a property. More specifically, we explored all the properties present in a class, and interquartile range of string literals lengths distribution for constraints generation. We evaluate the minLength using 1st quartile(Q1) and maxLength using the first quartile (Q3). Table 5 illustrates the string length conditions for minLength and maxLength. In particular, we mainly focus on identifying a relative range for the maximum and minimum length. An example of string length cosed SHACL Shape for *dbo:title* property is presented in Uisting 4.

5. Approach

In order to formulate an answer to the research questions, an approach is designed to identify KB with completeness and consistency issues. Based on the data profiling information, a set of features is introduced taking into account completeness and consistency analysis. These features are applied in the learning models to create RDF shapes. Figure 3 illustrates the process flow of the proposed approach that is divided in three main stages:

(*i*) Data Collection: A data curator needs to select an entity type to initiate the completeness analysis procedure. Then, the process checks the chosen entity types present in all KB releases to verify schema consistency and computes the summary statistics.

(ii) Data Preparation: The features are generated using the results from data profiling.

(iii) Modeling: The validation of the hypothesis is performed using quantitative and qualitative analysis. Also, the performance of the constraints classifiers is assessed using learning models.

Figure 4 illustrates the completeness and consistency analysis workflow that is outlined in Figure 3. The stages are explained in details below.

5.1. Data Collection

In this approach, the history of KB releases and summary statistics are applied as inputs to the completeness and consistency analysis. The acquisition of KB releases is performed by querying multiple SPARQL endpoints (assuming each release of the KB is accessible through a different endpoint) or by loading data dumps. For each KB releases, summary statistics are generated using data profiling. The Data Collection component is built on top of Loupe [70], an online system that inspects and extracts automatically statistics about the entities, vocabularies (classes, and properties), and frequent triple patterns of a KB.

In this component, preprocessing operations is perfomed over the collected dataset based on schema consistency checks. It is essential to perform the schema consistency checks due to high-level changes are more schema-specific and dependent on the semantics of data. Hence, this component does the following tasks: (*i*) selection of only those entity types that are present in all KB releases, and (*ii*) for each entity type, selection of only those properties present in that class. For example, in the implementation, the properties are filtered for an entity type in the the instance count is 0 for all the KB releases.

5.2. Data Preparation

The goal of this stage is to extract the completene. and consistency features for quantitative and qual cativ - analysis. These automatically generated features are further alid led using manual validation (which is a human Jriven ta. s). The data preparation process is divided into tros. res: (i) feature extraction; and (ii) manual validation. The feature extraction component is based on evolution bar ed c mpleteness analysis, and integrity constraints based convirtency analysis. The entity types with completeness issues are considered as input to the constraints based feature extraction process. Then, this feature dataset is used for integrity constraints based evaluation tasks. Furthermore, qualitative analysis is performed using manual validation to eval ate the precision of completeness measure. Also, the features are man ally evaluated to create a partial gold standard. The components are explained in detail below.

5.2.1. Feature Extra tion

A feature extraction vsk is performed to instruct the learning models. It is composed of two stages: (*i*) selecting an entity type using the completeness measure results, and (*ii*) constraints based shape induction to compute the features. The features are four in total and they are grouped into two categories as shown in Table 6.

Table 6: Features based on quality issues.

Quality Issues	Feature	Classifier Values
Completeness	Property	(0,1)
Consistency	Minmum Cardinality	(MIN0,MIN1+)
	Maximu A Ca linality	(MAX1, MAX1+)
	Range	(IRI,LIT)

i) Completeness f. "tw 2s: These features are extracted using evolution based complete ress analysis 4.2). In particular, using the selected class a 1 properties from schema consistency check, complete ress is neasured by comparing the changes present in the current release with respect to the previous release. The result of the completeness features is indicated by a Boolean value $0 \le c$ 1: 1 indicates a normal growth, while 0 indicates all unstable behaviour (Table 2).

ii) Consisten y features: These features are based on the results from integrity constraint checks that are derived from the SHAC, representation (Section 4.3). In particular, the experiminantly sit is based on cardinality, and range constraints. Moreover, the cardinality constraints is divided into minimum a maximum cardinality constraints. In particular, this phase we duate the constraints based feature dataset using three consumpts: *i*) Properties with minimum cardinality values of MIN0 \sim MIN1+; *ii*) Properties with maximum cardinality values of MAX1 or MAX1+; *iii*) Properties with range values of LIT or IRI. Finally, each of this feature is used as inputs and applied in supervised learning models to evaluate the constraints based classifier performance.

5.2.2. Manual validation and gold standard creation

The main goal of this step is to extract, inspect, and perform manual validation to identify the causes of quality issues as well as create gold standard. Manual validation tasks are based on the following three steps:

i) Instances: For manual validation, a portion of the properties with quality issues is selected using the completeness analysis. The selection is performed in a random fashion to preserve the representativeness of the experimental data. The proposed completeness and consistency analysis is based on the results of statistical data profiling to identify any missing entities. Based on the quantitative analysis results, in this step, all entities are extracted from the two releases of a given KB and set disjoint operation is performed to identify missing entities.

ii) Inspections: Using the dataset from instance extraction phase, an inspection of each entity is performed for manual validation and report. Various KBs adopt automatic approaches to gather data from the structured or unstructured data sources. For example, the DBpedia KB uses an automatic extraction process based on the mapping with Wikipedia pages. For the manual validation, a source inspection is performed using the missing instances to identify the causes of quality issues. In particular, a manual evaluation checks if the information is present in the data sources but missing in the KB.

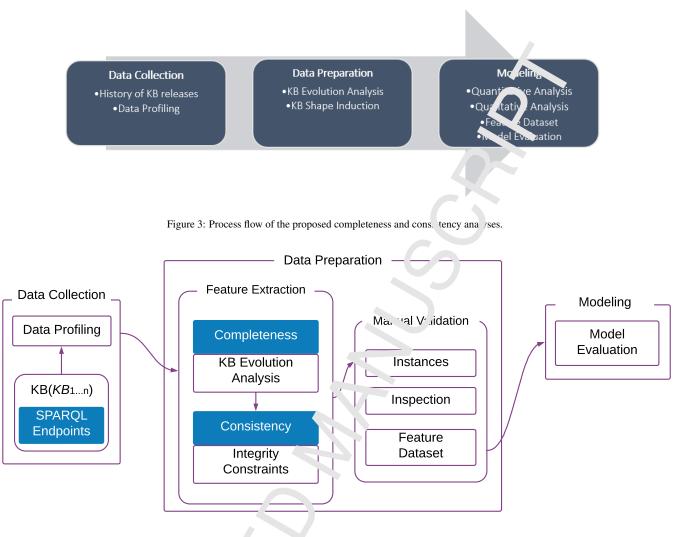

Figure 4: V orkfl/ w of the completeness and consistency analyses.

iii) Report: the validation result of an *ity* is reported as true positive (the subject presents an issue, and a actual problem was detected) or false positive (the i.e. presents a possible issue, but none actual problem is four *i*).

In this approach, a partial gold st ndara trategy (Sec. 2.3) is adopted based on the assumption that *e* new (small) training set is needed when dealing with a new transformed dge base. The manual validation phase is then in change of the spectra and performing a manual annotation of the detect of integrity constraints. In detail:

(*i*) *Feature extraction*: At first the entities and properties are selected from the competeness : halysis results for constraints based feature extraction. Then it selects the properties annotated with integrity (magning for further inspection.

(*ii*) *Inspection*: the v. '.dation result of an instance is reported as *Correct* (the propertie, are annotated with correct integrity constraint) or *Incorrect* (the item presents a wrong integrity constraint).

(ii) Feature dataset: the outcome of the manual validation tasks is a subset of the feature dataset according to each in-

tegrity constraints. This dataset is considered as the training set for the modeling phase.

5.3. Modeling

In this phase, five learning models are applied to evaluate the performance of the cardinality and range constraints classifier by computing precision, recall, and F-measure (Sec. 2.4). The modeling task is run with a *10-fold cross validation* setup in standard settings. The performance is measured using five classical learning models (Section 2.4). These models are selected to evaluate classifiers performance considering the diversity in machine learning algorithms and to identify the best performing model. Based on the empirical analysis the best performing model is applied for the prediction tasks.

6. Experiments and Evaluations

This section describes the experiments performed on two KBs, namely DBpedia (both English and Spanish versions) and 3cixty Nice. We first present the experimental setting of the implementation, and then, we report the results of both (i) completeness analysis based on dynamic features and (ii) consistency analysis using integrity constraints.

6.1. Experimental Settings

We selected 3cixty Nice KB and DBpedia KB according to: (*i*) popularity and representativeness in their domain: DBpedia for the encyclopedic domain, 3cixty Nice for the tourist and cultural domain; (*ii*) heterogeneity in terms of content being hosted such as periodic extraction of various event information collected in 3cixty Nice KB, (*iii*) diversity in the update strategy: incremental and usually as batch for DBpedia, continuous update for 3cixty. In detail:

- *3cixty Nice* is a knowledge base describing cultural and tourist information concerning the cities of Nice. This knowledge base was initially developed within the 3cixty project,²⁰ which aimed to develop a semantic web platform to build real-world and comprehensive knowledge bases in the domain of culture and tourism for cities. The KB contains descriptions of events and activities, places and sights, transportation facilities as well as social activities, collected from local and global data providers, and social media platforms.
- *DBpedia*²¹ is among the most popular knowledge bases in the LOD cloud. This knowledge base is the output of the DBpedia project that was initiated by researchers from the Free University of Berlin and the University of Leipzig, in collaboration with OpenLink Software. DBpedia is roughly updated every year since the first public release in 2007. DBpedia is created from autom tically 'xtracted information contained in Wikipedia,²² with as infobox tables categorization information, geo-coordinates, and external links.

Following we present a detailed summery of the _xtracted datasets for each KB.

3cixty Nice. In the data collection module, we used the private SPARQL endpoint for the 3cixty Nice KB. We collected two datasets: (*i*) 8 snapshots based on c_1^{-1} 3cixty Nice release, and (*ii*) daily snapshots over the period of 2 months. The 3cixty Nice KB schema [21] remained u char ged for all eight releases collected from 2016-06-15 to 2016- 9-0°. We collected those instances having the *rdf:type intode:Event* and *dul:Place*. The distinct entity count for *lode Event* and *dul:Place* is presented in Table 7. Overall, we collected from 192 distinct properties for the *lode:Event* typed entities and 192 distinct properties for the *dul:Place* typed entities are ross eight different releases. Furthermore, to monitor the science of *lode:Event* entity type from 2017-07-27 to 2⁻¹/-09-16. The daily snapshots values are collected without co. sidering distinct count to investigate

the changes present in the data extraction pipeline. Table 8 reports the entity count of *lode:Event* type using periodic snapshots generation.

DBpedia. We collected a total of 11 DBpedia releases from which we extracted 4477 unique properties. For this analysis we considered the following ten classes: *dbo:Animal*, *dbo:Artist*, *dbo:Athlete*, *dbo:Film*, *dbo:MusicalWork*, *dbo:Organisation*, *dbo:Place*, *dbo:Species*, *dbo:Work*, *foaf:Person*. The above entity types are the most common according to the total number of entities present in all 11 releases. Table 9 presents the breakdown of entity count per class. We also explored the Spanish version of DBpedia to further validate our completeness measure. In Table 10, we present the *dbo:place* class entity count across the seven releases of the Spanish DBpedia.

6.2. Completeness Evaluation

In this section, we report the completeness evaluation results for both KBs. The general goal of this experimental analysis is to verify that *dynamic features using periodic profiling can help to identify completeness issues*. We perform the quantitative and qualitative completeness analysis. Table 11 reports the criteria used for the completeness evaluation. At first, we perform quantitative evaluation using the evolution-based completeness analysis (Section 4.2). Then, in the qualitative evaluation, we

6.2.1. 3cixty Nice

Based on the entity counts reported $T_{able 7}$, we applied the linear regression over the eig' crelear s for the *lode:Event*-type and *dul:Place*-type entities. We pres nt the regression line in Figure 5 and 6.

From the linear regression, the 3cixty Nice has a total of n = 8 releases where the 8^{th} , redicted value for *lode:Event* $y'_{event_8} = 3511.548$ while the actual value=689. Similarly, for *dul:Place* $y'_{place_8} = 47941.57$ and the actual value=44968.

The residuals, $e_{events_i} = |689 - 3511.548| = 2822.545$ and $e_{places_8} = |44968 - 49741.5.1| = 2973.566$. The mean of the residuals, $e_{event_i} = 125.1784$ and $e_{place_i} = 3159.551$, where i = 1...n.

So the normalized distance for the 8th lode:Event entity $ND_{event} = \frac{2822.545}{125.1784} = 22.54818$ and dul:Place entity $ND_{place} = \frac{2973.566}{3159.551} = 0.9411357$.

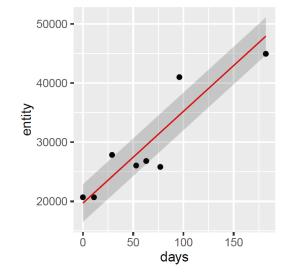

Figure 6: dul: Places class regression line using entity counts over 8 releases.

For the *lode:Event* class, $ND_{events} \ge 1$ so the KB growth measure value = 1. However, for the *dul:Place* class, $ND_{places} < 1$ so the KB growth measure value =0.

In the case of the 3cixty Nice KB, the *lode:Event* class clearly presents anomalies as the number of distinct entities drops significantly on the last release. In Figure 5, the *lode:Event* class growth remains constant until it has errors in the last release. It has higher distance between actual and predicted value based on the *lode:Event*-type entity count. However, in the case of *dul:Place*-type, the actual entity count in the last release is near to the predicted value. We can assume that on the last release the 3cixty Nice KB has improved the quality of data generation matching the expected growth.

We then performed an empirical analysis by monitoring the 3cixty KB lode: Event entity type. To monitor any changes present for continuous updates, we collected 50 snapshots of lode: Event entity type from 2017-07-27 to 2017-09-16. Table 8 reports the entity count of lode: Event class 50 snapshots which is collected using the 3cixty KB SPARQL endpoint. Figure 7 illustrates the changes presents in the lode: Event-type due to KB growth, and Figure 8 reports the regression line using entity count. There are significant changes present in the last four releases (2017-09-13, 2017-09-14, 2017-09-15, 2017-09-16) entity count. In the 2017-09-13 release, we can see an exponential growth of actual entity count value of 190,187 compared to predicted value of 125,100. Furthermore, on the next two releases (2017-09-14,2017-09-15) entity count remains stable due to fewer variation presents in the entity count. However, on the 2017-09-16 snapshots, we can observe a drop in the ertity count which may lead to anomalies in the data integration. pipeline. We further investigated the value chain leading to the generation of the KB, and we found an error in the external Crta acquisition process that led to missing entities for the 2017-09-16 snapshot.

To validate our assumptions, we perform property comple eness measure based on the last two KB releases, nan. 1v 20 5-05-15 and 2016-09-09. In Table 12, we present a subsuit of completeness measure results. For the *lode:F ent* intit type, the number of predicates in the last two releases - ?1 and the number of predicates with completeness is regions (value of 0) = 8. For instance, *lode:Event* class property *at. 'lace* ... ' a frequency of (1,632,424) for the releases 2016-6-5 and 2016-09-09. Based on the condition of complete^r ess r leasure (Table 11), the property lode: at Place indicates a cumpleteness issue. In Table 13, we present completeners measures based on 50 periodic snapshots. For example, on he frequency count of *lode:BusinessType* in the 2017-09-15 napshot the observed value is (1,74,421) lower t an 20.7-09-16 snapshots value (99,996). In this account, the completeness measure value is 0 leading to possible quality issue.

6.2.2. DBpedia

We evaluate the KB update trends based on linear regression analysis by con paring with actual and predicted values. In this account, we meal ured the normalized distance (ND) for each class. Based on the normalized distance, we then classify the growth of the class. Based on the entity counts reported in Table 9, we applied the linear regression for each class. Table 14 illustrates the normalized distance and predicted growth values for each class. From the results obTable 12: Completeness measure of the 3cixty Nice lode: Event class.

Property	2016-05-15	2016-09-09	Complete	
lode:atPlace	1,632	424	0	
lode:atTime	2,014	190	0	
lode:businessType	2.82	689	0	
lode:hasCategory	1,6>	584	1	
other rear are o. itted for brevity				
lode:involvedAger	266	42	0	

served for dbo:/ rtist, / oo:Film, and dbo:MusicalWork, the normalized $_{\text{ustance 1s}}$ near the regression line with ND <1. We as up tha these classes have stable growth. On the contrary, dbo Animal, dbo:Athelete, dbo:Organisation, dbo:Place,ac .: Species, dbo:Work, and foaf: Person, the normalized C stance is far from the regression line with ND > 1. We assume the fast release these classes might have unstable grow.' which may lead to completeness issue. For example, Trure 9 reports the *foaf:Person* class regression line using entity curnts over 11 releases. The foaf: Person-type last release r particular, foaf: Person has KB growth measure of 1 with a no. malized distance ND = 2.08. From this measure, we can purceive that in *foaf:Person* there is completeness issue. We an imply that additions in a KB can also be an issue. It can be due to unwanted subjects or predicates.

To further evaluate our assumption, we perform property completeness analysis based on the last two DBpedia KB releases of 201510 and 201604. Table 16 reports the results of completeness based on the latest two releases of DBpedia 201510 and 201604 for foaf: Person entity type. foaf: Person has a total of 436 properties over the two considered versions. The number of consistent properties is 238. Based on the completeness criteria (Table 11), we computed the completeness measures over those 238 properties and identified 50 properties with completeness measure value of 0. The remaining 188 properties can be considered as complete. For example, the *foaf:Person* class property dbo:firstRace has an observed frequency of 796 in the 201510 release, while it is 788 in the 201604 release. As a consequence the Completeness measure evaluated to 0; thus it indicates an issue of completeness in the KB. We further validated our results through manual validation. Table 17 reports, for each class, the total number of properties - which were detected by completeness computation -, the complete properties, the incomplete properties and percentage of complete properties.

Taking into account the Spanish DBpedia on the last two releases (201604, 201610) there are in total 8, 659 common properties present in the datasets. We identified 3, 606 properties with quality issues based on the frequency difference between two releases. In Table 15, we present a subset of completeness measure results. We have detected quality issues based on the property frequency difference between two versions of the

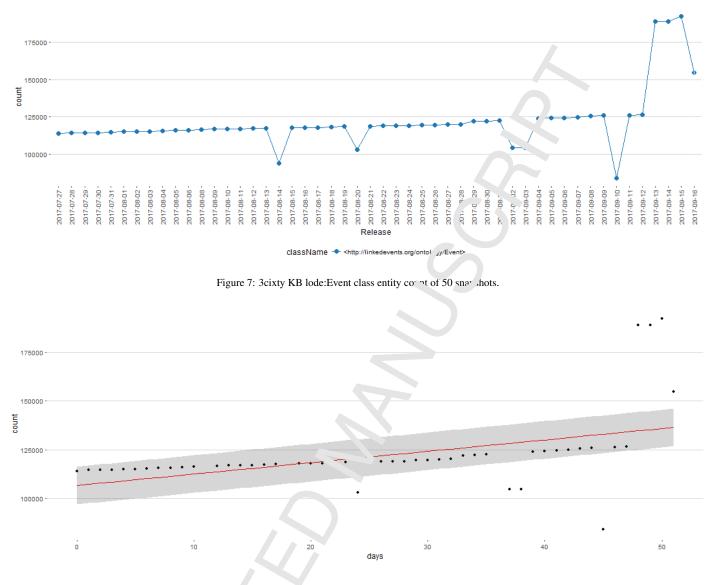

Figure 8: 3cixt^{*}, ^{*} lode:Event class regression line using entity count of 50 snapshots.

dbo:Place class. For ex mple, the property *dbo:anthem* count is 316 for the 201610 release while it was 557 in the 201604 release. This variation in the property count implies that 241 resources are missing in the 201610 version of the DBpedia 201610 release. We further validated this result through man-

ual validation.

6.3. Manual Validation

We manually inspected whether the detected issues by the Feature Extraction stage are real issues. We annotated each

explained in detail below.

lode:Event **properties:** In the last two releases of *lode:Event* class we found 21 common properties. From this list, we found only eight properties have completeness value of 0.

Instances. We investigated all entities attached to this eight properties and we extracted five instances for each property, in total we manually collected 40 different entities.

Inspection. We observed that entities that are present in 2016-06-06 are missing in 2016-09-09. Thus, it leads to a completeness value of 0. As a result we identified a total of 1,911 entities missing in the newest release: this is an actual error. We further investigated and found an error in the reconciliation algorithm for 2016-09-09 release. In this account, the variation present in the stability measures is true positive. Furthermore, based on the True Positive and False Positive results, the output from completeness measure has a precision of 95%.

foaf:Person/dbo:firstRace property: For the *foaf:Person* entity type, we found 238 common properties in last two releases (201510, 201604) for the English DBpedia KB. From the completeness measure over 396 properties only 131 properties have a completeness value of 0.

Instances. We investigated a subset of 50 incomplete properties based on the subjects present for each property. For exam-

 $^{^{23}}$ We remind here that the intent is to be precise, rather than maximizing the quantity of the annotations. We have studied empirically that a good number of annotations is 250 and demonstrated by the experimental results.

ple, property *dbo:firstRace* and *dbo:lastRace* have completeness value of 0. We extracted all the subjects present in the last two releases (201510 and 201604) and performed a set disjoint operation to identify the missing subjects. For manual validation, we first checked five subjects for the *dbo:firstRace* and *dbo:lastRace* property, checking a total of 250 entities.

Inspection. In the 201604 release, dbo:firstRace has 769 instances and in the 201510 release it has 777 instances. After the set disjoint operation between two releases (201510, 201604), we found 9 distinct instances missing in 201604 release of the English DBpedia version. Furthermore, we manually inspected each instance to identify causes of incompleteness issue. One of the data instance dbr:Bob_Said for the dbo:firstRace property is available in the 201510 release. However, it is not present in 201604 release. We further explore the corresponding Wikipedia page using *foaf:primaryTopic*. In the Wikipedia page firt race is present as info box key. Due to DBpedia update from 201510 to 201604 version, this entity has been missing from the property *dbo:firstRace*. Similarly, we also found this entity is missing for the *dbo:lastRace* property. This presents an ideal scenario for completeness issues in the 201604 release of the English version of DBpedia. Based on the manual inspection of 50 properties, we observed that completeness measure has the precision of 94%.

dbo:Place/dbo:prefijoTelefónicoNombre **property:** From the Spanish version of DBpedia, *dbo:Place* entity type conpleteness measure we found 3, 606 properties with completeness value of 0. This indicates a potential completeness a sucpresent for these properties.

Instances. From the 3,606 property, we randomly solveted the property *dbo:prefijoTelefónicoNombre* for may all validation. We collected all the subjects (56109, 55387) from the two releases (201604, 201610). Then we perform d a set of disjoint operations between two triples set to ider. 'fy' nose riples missing from the 201610.

Inspection. From the set disjoint operation, re-found a total of 1982 subject missing from 201610 version. To keep the manual work at a feasible level, we selected a subset of 200 subjects for evaluation in a random manner. U. o of the results of the analysis is location Morante,²⁴ whi n is avai. ble in the 201604 release. However, it is missing in 2/161^r release of DBpedia. To further validate such an ou_{k} , we checked the source Wikipedia page using foaf:pr maryTopic about Morante.²⁵ In the Wikipedia page prefijo 7 lefónico Vombre is present in the infobox as key. In the Spanish Pneria from 201604 version to 201610 version update, his subject has been missing from the property prefijo Telefóni oNombi . This example shows a completeness issue presents in the 201610 release of DBpedia for property prefijo Tele one "onbre. Based on the investigation over the subset of pro, ^o ty values, we compute our completeness measure has the prevision of 89%.

6.4. Consistency Evaluation

The process leading to the constraint definitions is outlined in Section 4.3. From the quantite are analysis, we have identified multiple entity types and pr_{2k} rties with quality issues. In particular, we selected the entity types from the completeness analysis for consistency analosis in devaluated the performance of the constraint classifier wing rive learning models. Our approach has been implemented with a prototype written in R.²⁶

Feature Extraction. We the evaluating the integrity constraints evaluation as a constitution problem, it is necessary to further validate the armotations and create a gold standard. In this context, we have normally inspected the constraints feature (Section 5.1.1) values from the 3cixty and DBpedia KB. However, to keep the minual inspection tasks at the feasible level, we have relevant a subset of properties for an entity type.

In this e perimential analysis for the English DBpedia KB, we used the expect d cardinalities for 174 properties (associated with a instance of a given class). Also, we collected a subset of 200 properties associated with the *dbo:Place* entity type for PLo' jects and the datatype for literal objects. Similarly, Properties and 219 properties for the range constraints based on *dbo:Organization* entity type. Furthermore, we colinstances of a given class for 215 properties for the 3 city Nice KB. For range constraints, we collected 215 propties associated with IRI and the datatype for literal objects. Following we present an example of feature extraction process based on minimum cardinality, maximum cardinality and range constraints.

Cardinality constraints: We generate cardinality information for each property associated with the instances of a given class. For example, by analyzing 1,767,272 *dbo:Person* instances in DBpedia, we extract the cardinality distribution for *dbo:Person-dbo:deathDate* as reported in Table 18.

Table 18: Cardinality Counts for dbo:Person-dbo:deathDate.

Cardinality	Instances	Precentage
0	1,355,038	76.67%
1	404,069	22.87%
2	8,165	0.46%

During the feature extraction step, this raw profiling data is used to derive a set of features that can be used for predicting the cardinality. Another example of cardinality distribution is reported in Table 19 for the *dbo:Sport/dbo:union* property.

At first we extract the raw cardinalities. Based on the raw values, we compute the distinct cardinality values

²⁴http://es.dbpedia.org/page/Morante

²⁵https://es.wikipedia.org/wiki/Morante

²⁶ https://github.com/rifat963/RDFShapeInduction

Table 19: Cardinality	Counts for	r dbo:Sport/dbo:union.
-----------------------	------------	------------------------

Cardinality	Instances	Precentage
0	1,662	84.88%
1	279	14.14%
2	10	0.05%
3	5	0.02%
4	2	0.01%

distributions similar to the ones reported in Table 19. Note that there are three distributions, one is the raw cardinalities (0,1,0,3,1,2,1,6,1,0), then distinct cardinalities (0,1,2,3,4) and the percentages of instances per each cardinality (84.88%, 14.24%, 0.05%, 0.02%, 0.01%). Further, for each of the three distributions we derive 30 statistical measures including min-max cardinalities, mean, mode, standard deviation, variance, quadratic mean, skewness, percentiles, and kurtosis [68].

Table 20 reports 30 features (P1 to P30) selected for a classifier that predicts the cardinality category with example values for the dbo:Sport class dbo:union property. Features P1 to P13 are related to raw cardinality distribution, features P14 to P20 are related to the distinct cardina¹ity distribution, and features P21 to P30 are related to the percentage distribution. For example, P1 presents a minimum cardinality value of 0 for dbo:Sport/dbo:union . a P2 presents maximum that is 4. Our intuition is that these are descriptive to classify the cardinality categor Nevertheless, the data can be noisy and either min r/and n ix could be outliers. To address this we add stan, "cal f atures that give more insights about the dist ibution of the cardinalities such as mean, mode, kurto s, s and d deviationsm, skewness, variance and four percentills. Our motivation for using these statistical plues is that each of these could provide some insights related to different possible cardinality distributions. Las 1 on the cardinality level (Sec. 4.3), we create a gol star dard by annotating the properties with corresponding constraints values and create the feature dataset for /alic ation. For instance, the dbo:Person-dbo:deathDate ... rr spor ling SHACL property constraints are generated as in trated by Listing 1.

Range Constraints: We collected stitistics about the number of IRIs, Literals, and Bland notices for each property associated with instances of a given class as shown in Table 21. The blank node colling are also generated by the data collection stage but they are not reported because there were no blank nodes in university.

Furthermore, we lso explore object type information by analyzing all hAI and blank node objects. Table 4 shows an example of object type information by analyzing all objects having *dbo:Person/dbp:deathPlace* as class-property. As it can be seen, the objects of *dbo:Person/dbp:deathPlace* are typed as many different Table 20: *dbo:Sport/dbo:union* 30 statistical measures (p1 to p30) from raw cardinality estimation.

ID	Description	Example	د ۲	Description	Example

dbo:Person/dbp:religion	8,374	786	6,977	407

classes. And, in general, it can be seen that most objects are typed with multiple classes (e.g., with equivalent classes, super classes). Also there are some objects that should not be associated (*i.e.*, inconsistent) with the *dbp:deathPlace* property, for example, a *Broadcaster* should not be a death place of a person. Further, there are some objects for which the type information is not available.

Similarly, for literal objects our data collection module extracts the information about their data types. Table 23

Object Class	Objects (89,355)		Distinct Object (21,845)

We use all the aforementioned ir orm tion as features for the two tasks of detecting the object we and also detecting the class type for IRI objects ar 1 the datatype for literal objects.

String constraints: We use *i* atistic about the literals to identify the minLength and maxLer th of the string values. Based on the string lenge discribution of literal values, we explore the 1st quartile and 3rd quartile to identify the minimum and naximula length. More specifically, we evaluate the intergrammer and range (IQR) based on the string length light intergrammer of a property. For example, in Table 24, we report the string length distribution of the *foaf:Person* clas. *dbo:Title* property together with frequency of string length. Similarly, in Table 25, it is illustrated the *dbo:BirthName* property frequency distribution.

In this example, both properties have a small central tendency towards the mean. Our main focus is to identify a Table 24: Frequency distribution of *foaf:Person/dbo:Title* property.

String Length	Frequency	Percentage
16	20	31.25 %

range of minLength and maxLength for literal objects. In this account, we use the interquartile range for *dbo:title* to identify minLength and maxLength. We used the 3rd quartile (Q3) of the string length as maxLength and the 1st quartile (Q1) as minLength for the *dbo:title* property. In Figure 10, we present a boxplot of the *dbo:title* property. In particular, using the interquartile range, we can present the string range constraints as a binary classifier.

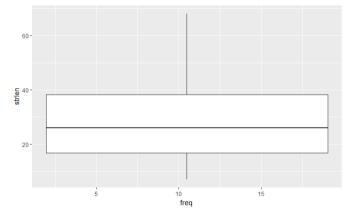

Figure 10: foaf:Person class dbo:title property string length box plot.

Model Preparation. From the initial analysis of the feature dataset, we found that the minimum cardinality constraint has an imbalance in distribution of feature values. We observed that rare events occur in case of selected constraints as response variables. The variation between two variables is less than 15%. We applied SMOTE (Synthetic Minority Over-sampling Technique) [71] for oversampling the rare events. The SMOTE function over-samples response variables by using bootstrapping and k-Nearest Neighbor to synthetically create additional

observations of that response variable. In our experiment, we applied an over-sampling value of 100 to double the number of positive cases, and an undersampling value of 200 to keep half of what was created as negative cases. It balances the classifier and achieves better performance than only under-sampling the majority class. The results are reported in Table 26. After applying the SMOTE technique, we applied 10-fold cross-validation based on the learning models mentioned in Section 2.4.

Model Evaluation. In detail, the model evaluation results are mentioned below.

- *3cixty Nice.* Table 27 reports the 3cixty KB three constraints classifier performance measures. Considering five learning models, the Random Forest model had more than 90% of F1 value for all three classifiers. For minimum cardinality, the Random Forest model reached 91% F1 score where it achieved 96% precision. Conversely, the Neural Network model reached 90% F1 score for range constraints. However, simple Naive Bayes learning algorithm had a significantly lower F1 (<70%) score compared to the other classifiers. K-Nearest Neighbour (K-NN) had the lowest F1 score for the maximum cardinality and range constraints.
- English DBpedia. Table 27 illustrates the three classifiers performance measures for the English version of tl. DBpedia KB. Similar to the 3cixty KB, Random Forest proved to be effective in achieving greater than 90 T¹ value for all three classifiers. Overall, for Random Fores, algorithm, minimum cardinality constraints reached 97% F1 score where it achieved 98% precision. A so, in the case of minimum cardinality classifier, other parning lgorithms such as Neural Network and Least Square, S' M reached an F1 score greater than 90%.
- Spanish DBpedia. Table 29 reports the integrate constraints performance measure for the Chanish DBpedia Dataset. Compared to the other models, kall dom Forest achieved the highest F1 score for all three classifiers. In addition, it achieved 92.85% F1 coort for maximum cardinality classifier. Compared to Rall three for an Forest model, Least Squares SVM also achieved the F1 score of 87.23% for the minimum cardinality of ssift r. For the Spanish DBpedia KB, Naive Barton classifier that the lowest F1 score for all the constraints classifiers.

7. Discussion

In this section, we discult 1^{-1} c main findings and the limitation of this work using una coults from the experimental analysis (Section 6). Figure 1, illustrates the primary results of this work labeled with A, B, $\ D$, and E.

7.1. Completeness Analysis

We perceive that changes observed in a set of KB releases can help in detecting completeness issues. We identified properties with quality issues based on dynamic features from the completeness analysis. We, then, summarize our assumption using qualitative analysis by manually evaluating a subset of classes and properties. From the experimental analysis, we potentially detected errors in various stage: of evelving KBs. Following we summarize our findings baser the completeness evaluation.

• Causes of Quality Iss. 's, ' rom our completeness evaluation, three types of quality insues are identified: (i) errors in the data extraction process, (ii) erroneous conceptualization, and (iii) error in object type. In details:

Errors in the date. γ iraction process: We discovered properties with γ analies and performed further inspections for each K!. For the 3cixty KB *lode:Event* entity type, we identified complete less issues due to an algorithmic error in the γ are extraction pipeline. For what concerns DBpedia, $w \in id$ ntited issues as a result of missing mapping with Wikipedⁱ, infobox keys. This issue of missing mapping maght happened because of wrong schema presentation or schema definition inconsistency due to KB updates.

Froncess conceptualization: We observe that the properties . 'th lower frequency tend to have erroneous schema representations. For example, the property *dbo:weight* ha. 4 data instances mapped with *dbo:Place* type. We suffer investigated each of this data instance and corresponding Wikipedia page. From manual investigation, we identified *dbo:weight* property erroneously mapped with the *dbo:Place* type. Such as one of the data instance *wikipedia-en:Nokia_X5* is about mobile devices, and it is mapped with *dbo:Place* type. This mapping indicates a consistency issue as a result of a wrong schema presentation.

Error in object type: From the manual validation results, we assumed that it could be possible to identify an error in any literal value using our approach. For example, the property dbo:bnfld triggered a completeness issue. We, therefore, further investigated the property *dbo:bnfId* in the 201604 release. We explored the property description that leads to Wikidata link²⁷ and examined how BnF ID is defined. It is an identifier for the subject issued by BNF (Bibliothèque nationale de France). It is formed by eight digits followed by a check digit or letter. Based on the BnF ID formalization rule, we checked each literal values for *dbo:bnfId* entity type. We found that one of the literal values is "12148/cb16520477z" for subject Quincy_Davis_(musician)²⁸ contains a "/" between the digits "12148" and "cb16520477z", which does not follow the standard formatting structure issued by BNF (Bibliothèque nationale de France). It clearly points to an error for the subject Quincy_Davis_(musician). However, to detect errors in literal values, we need to extend our quality assessment framework to inspect literal values computationally. We considered this extension of literal value analysis as a future research endeavor.

• Summary of findings. In the case of t e 3cixty Nice KB, we only identified issues based on the data source extraction process. For example, we found a gnificant number of resources missing for th lod :Ev ut class in the last release(2016-09-09). We identify a three types of quality issues for DBpedia V B. For example, entities missing in *foaf:Person* class is the to incorrect mappings of field values in the data extraction process. Also, we identified a notable number c. issue: due to wrong schema presentation for the DB₁ dia KB Such as property *dbo:Lake* with wrong Winper infobox keys. Taking into account periodicity of KE we observe that continuously analyzing KBs with high-t, quency updates (daily updates), such as the 3cixty Nice KB, has fewer quality issues. On the other hand, KBs with low-frequency updates (monthly or yearly updates), such as DBpedia KB, seem to have more completeness issues.

Correspondingly, we analyze the KB growth patterns to predict any unstable behaviour. We define this lifespan analysis as *stability feature*. A straightforward interpretation of the stability of a KB is monitoring the dynamics of knowledge base changes. This dynamic feature could be useful to understand high-level changes by analyzing KB growth patterns. However, a further exploration of the KB stability feature is needed, and we consider this as a future research activity.

Overall, we evaluated the property completeness measure in terms of precision through manual evaluation. Considering computational complexity, we only use count and difference operation for measurement functions. We assume that our computational complexity will be $O(N_T)$ where the N_T is the total number of entities for type T. The computed precision of completeness measure in our approach is: *i*) 94% for *foaf:Person*-type entities of the English DBpedia KB; *ii*) 89% for *dbo:Place*-type entities of

Table 29: Integrity Constraints performance measure for Spanish DBpedia.

Problem Definition

In the current literature, quality assessment for evolving KBs using $\cos \varepsilon - \alpha$ and analysis is not fully explored. The two main issues explored in this study: (1) identification of completeness is using evolution analysis, and (2) identification of consistency issues based on integrity constraints

Research Question (RQ)

RQ1: To what extent the periodic profiling of an evolving KB Concomposite to unveil completeness issues? RQ2: How can we perform consistency checks using integrity contraints as predictive features of learning models?

Hy_., thes 's(H)

H1: Dynamics features from periodic data profiling can h. to us identify completeness issues. H2: Learning models can be used to predict correct integrity constraints using the outputs of the data profiling as features.

Results

A: Quantitative and qualitative analysis f $r \operatorname{com}_{P}$. \dagger ness evaluation.

B: Completeness analysis using dynamic fer tures was able to achieve greater than 90% precision in error detection for both the use cases.

C: Integrity constraints based featur / extraction using data profiling.

D: Accessing the performance of t'. Consistency analysis by using five learning models over three sub-tasks, namely minimum cardinality, maximum cardinality and range constraint.

E: The best performing model *i*, *u*, experimental setup is the Random Forest, reaching an F1 value higher than 90% for minimum and maxim m cr, dinality, and 84% for range constraints.

Figur. 1. Sur nary of the main results of the Completeness and Consistency Analysis.

the Spanish DBpedia K1 and *iii* 95% for the *lode:Event*-type entities of the 3^{-1} ty New KB.

7.2. Consistency Analys's

In the consistency analysis, the constraint classifiers performance is measured up procision, recall and F1 score. Overall, our constraints classifie. achieved high predictive performance with the Random Forest nuclei. For example, the Random Forest cardinality classifiers achieved the highest F1 score for all KBs. Furthermore, the Multilayer Perceptron and the Least Squares SVM also achieved high F1 scores greater than 90% for the English DBpedia KB. Concerning the range constraints, we explored the object node type constraint for each property associated with a given class. Similar to cardinality constraints, Random Forest algorithm achieved a high F1 score of 95.94% for the English DBpedia KB. This makes the consistency evaluation approach adaptable and facilitates adoption for multiple KBs.

Furthermore, we applied a Naive Bayes classifier. The model provides apriori probabilities of no-recurrence and recurrence events as well as conditional probability tables across all attributes. We considered Naive Bayes as a baseline model to explore the classifier performance compared to other learning algorithms. In this context, other models achieved better performance values compared to the Naive Bayes learning algorithm.

Finally, we generate constraints once the constraint prediction models are built. Based on the Random Forest model, we created the constraints datasets. More specifically, we combined all the constraints related to a given class and, for each, we generate an RDF Shape. An example of the RDF Shape in SHACL for the *foaf:Person* class is illustrated in Listing 5 using cardinality and range constraints. Furthermore, we perceived that the generated constraints datasets can be used in other tools such as RDFUnit [43]. We considered this extension of our RDF shape induction approach as a future work.

7.3. Limitations and Future Work

In this section, we discuss the lin static as of the proposed approach, together with future researc. d'rections.

Impact of addition of entit 28. A li. vitation of the current approach is that we only considered the negative impact of deletion of entities as causes of quark, issues. As a future research direction, we plan to study how to dynamically adapt impact of the addition of entitie in an evolving KB. Furthermore, we argue that quality issues can be identified through monitoring lifespan of a KB. This argument has led to conceptualize the stability feature, which is meant to detect anomalies in a KB. Using a simple linear regression model, we explore the lifespan of an entity type. We can envision that stability feature can be used for analyzing the impact of the addition of entities. As a future work, we plan to monitor various KB growth rates to explore stability feature. In particular, we want to investigate

further (*i*) which factors are affecting stability feature, and (*ii*) validating the stability measure.

Schema based validation. We presented experimental analysis using three constraints types: cardinality, range, and string. As a future work, we plan to extend our implementations to other SHACL constraints. With these constraints can be applied to other to its such as RDFUnit [43] as a direct input. However, in RDF out they considered constraints in the form of RDFS/OWL vioms. We considered extending our approach to RDF¹ m, as future research work to favor the interoperability.

Furthermore, in our c. perimental analysis, we involved a human annotator to validate the datasets in order to create the partial gold standards. As further work, we plan to extend our evaluation strategy with an internative approach such as the validation using CWL schema. However, it is challenging to explore an OWL schema for validation tasks. For example, the DBpedia KB 201610 monotology lacks axioms about cardinality constraints (ox 1:cardinality, owl:minCardinality, maxCardinality). In ponly if formation that we can extract from the ontology is indirectly using the axioms that define functional properties (i.e., MA 11 constraints). In this context, we plan to extend out approach to other KBs that contain complete OWL schema representations.

8. Conclusions

The primary motivations of this work are rooted in the concepts of Linked Data dynamics on the one side and constraints based KB validation on the other side. We focused on automatic shape validation as well as automating the timely process of quality issue detection without user intervention based on KB evolution analysis. Knowledge about Linked Data dynamics is essential for a broad range of applications such as effective caching, link maintenance, and versioning [9]. However, less focus has been given towards understanding knowledge base resource changes over time to detect anomalies over various releases. We introduced a completeness analysis approach by analyzing the evolution of a KB, to understand the impact of linked data dynamicity. More specifically, we explored the completeness of an entity type using periodic data profiling. However, we perceive that if the KB has design issues, our completeness analysis might lead to increase the number of false positives. We introduced an RDF validation approach to explore the consistency of KB resources using integrity constraints from SHACL representation. Our approach follows a traditional data mining workflow: data collection, data preparation, and model training. This approach can be applied to any knowledge base, and we demonstrated its usages for two different use cases, namely 3cixty Nice and DBpedia. We summarized the main findings of this work as follows:

In response to RQ1, the proposed approach provides an assessment of the overall completeness quality characteristic and it aims to identify potential problems in the data processing pipeline. Such an approach produces a smaller number of coarse-grained issue notifications that are directly manageable without any filtering and provide useful feedback to data curators. An experimental analysis of proposed completeness analysis is performed on two different knowledge bases of different size and semantics, and its operations are verified using these use cases. Since this approach uses simple statistical measures (count and difference), it reduces the search space of the suspicious issues, resulting in an approach that can be applied to also larger knowledge bases. Based on the two use cases, completeness analysis has proven to be highly effective to identify quality issues in the data extraction and integration process. Overall, the proposed approach achieved the precision of greater than 90% for completeness measures for almost all use cases.

To address RQ2, a consistency analysis approach is proposed using constraints based feature extraction and learning models. This approach is evaluated using cardinality, and range constraints. In the experimental analysis, the performance of the five learning models are empirically assessed and the best performing model is identified according to the F1 score. The proposed approach reaches an F1 score greater than 90% with DBpedia datasets for cardinality constraints using Random Forest model. Nevertheless, the proposed approach is defined in a generic and flexible manner which can be extended to other types of constraints. Overall, all learning models have good performances meaning that the problem is well configured and the features are predictive.
