Pencils of singular quadrics of constant rank and their orbits

ADA BORALEVI, EMILIA MEZZETTI

Dedicated to Giorgio Ottaviani on the occasion of his 60th birthday

ABSTRACT. *We give a geometric description of singular pencils of quadrics of constant rank, relating them to the splitting type of some naturally associated vector bundles on \mathbb{P}^1 . Then we study their orbits in the Grassmannian of lines, under the natural action of the general linear group.*

Keywords: Symmetric matrices, pencils of quadrics, general linear group, orbit.
MS Classification 2020: 14C21, 14M15, 14L30, 14F06.

1. Introduction

A *pencil of quadrics* in the projective space of dimension N is a two-dimensional linear subspace \mathcal{L} in the space of symmetric matrices of order $N + 1$, and it is a widely studied object in algebraic geometry.

A complete classification of pencils of quadrics, based on algebraic considerations, Segre symbols and minimal indices, has been known for a long time: we refer to the classical book by Gantmacher [9] and the expository article by Thompson [14].

There is also an extensive literature on geometric descriptions and interpretations of pencils of quadrics; among the many contributions, let us cite some older works, from [13] to [3], as well as more recent ones, such as [8].

Often, when studying pencils of quadrics in \mathbb{P}^N , one assumes that they are *regular*, that is, that they contain quadrics of maximal rank $N + 1$. As observed in [8], these pencils form an open subset in the appropriate Grassmannian, that admits a natural stratification by Segre symbols. The pencils in the complementary closed subset, called *singular pencils*, are less studied, even if in [9] it is shown that their analysis can be traced back to that of regular pencils and of singular pencils of constant rank. The purpose of this article is to give a description of the geometry of such pencils of constant rank, to relate it to the splitting of certain bundles on \mathbb{P}^1 naturally associated with them, and to give a description of their orbits under the natural action of the general linear

group $\mathrm{GL}(N + 1)$.

To be more precise, we set up our notations: we work over an algebraically closed field of characteristic 0, for simplicity over the complex field \mathbb{C} . Let V be a vector space of dimension $N + 1$ over \mathbb{C} . Denote by X the Veronese variety, that is, the image of the Veronese map $\mathbb{P}(V) \rightarrow \mathbb{P}(S^2V)$. The natural action of the group $\mathrm{GL}(N + 1)$ on $\mathbb{P}(V)$ extends to $\mathbb{P}(S^2V)$, and the orbits under this latter action are X and its secant varieties.

Fixing a basis for V , the elements of the vector space S^2V can be seen as symmetric $(N + 1) \times (N + 1)$ matrices: then the action of $\mathrm{GL}(N + 1)$ is the congruence, X corresponds to symmetric matrices of rank 1, and its k -secant variety $\sigma_k(X)$ to symmetric matrices of rank at most k .

Working in this projective setting, we interpret a pencil of quadrics as a line $\mathbb{P}(\mathcal{L}) \subseteq \mathbb{P}(S^2V)$: it is *singular* when it is entirely contained in the determinantal hypersurface $\sigma_N(X)$. If a singular pencil is entirely contained in a stratum $\sigma_k(X) \setminus \sigma_{k-1}(X)$, we say that the pencil has *constant rank k* . All the quadrics in such a pencil are cones having as vertex a linear space of dimension $N - k$.

In Section 2 we show that a pencil of constant rank k corresponds to a matrix of linear forms in two variables, that naturally defines a map of vector bundles of rank $N + 1$ over \mathbb{P}^1 ; since the rank is constant, the cokernel E of this map is also a vector bundle over \mathbb{P}^1 , of rank $N + 1 - k$, and its first Chern class is $\frac{k}{2}$; in particular the constant rank k is an even number that we denote by $2r$. We prove that the splitting type of E characterizes the orbits, and for each orbit we give two explicit constructions for the canonical form of the representative: one is the expression described in [9], the other one is analogous to the representative given in [7], adapted from the skew-symmetric case. Indeed, several techniques used in articles on spaces of skew-symmetric matrices of constant rank, such as [12, 2, 1], can be applied to pencils of quadrics.

Analyzing these canonical forms, in Section 3 we describe the geometry of the pencils in the various orbits. If we make the assumption that the bundle E has no trivial direct summand, which is equivalent to the condition that the quadrics in the pencil \mathcal{L} have no common point in their vertices, the pencil is called non-degenerate. In this case, if the splitting type of E is r_1, \dots, r_h , any two quadrics of \mathcal{L} have a generating space S of (maximal) dimension $N - r$ in common, and are tangent along a rational normal scroll of dimension r and type r_1, \dots, r_h contained in S .

In Section 4, we prove our main result Theorem 4.1: we find an explicit expression for the dimension of every $\mathrm{GL}(N + 1)$ -orbit of pencils of constant rank. We recall that these pencils are all unstable, nevertheless we are able to find an explicit expression for the matrices in the Lie algebra of the stabilizer of any pencil \mathcal{L} . In particular these Lie algebras all have dimension 5 when the corank of the pencil is 1, i.e. E is a line bundle with $c_1 = r$. In Proposition 4.6

we prove that they are of the form $\mathfrak{sl}_2 \times \mathbb{C}^2$. We conclude with a table collecting the results for $r \leq 6$.

2. Classification's details and first results

Recall from the Introduction that, given an $(N+1)$ -dimensional vector space V , one has the natural Veronese map $\mathbb{P}(V) \rightarrow \mathbb{P}(S^2V)$ sending $[v] \mapsto [v^2]$, whose image is the Veronese variety X . Once we fix a basis of V , the elements of S^2V are identified with symmetric $(N+1) \times (N+1)$ matrices, X corresponds to symmetric matrices of rank 1, and its k -secant variety $\sigma_k(X)$ to symmetric matrices of rank at most k . The group $\mathrm{GL}(N+1)$ acts by congruence on $\mathbb{P}(S^2V)$, and the orbits are exactly X and its secant varieties.

Now let $\mathbb{P}(\mathcal{L}) \subseteq \sigma_k(X) \setminus \sigma_{k-1}(X)$ be a singular pencil of quadrics of constant rank k . Notice that $\mathbb{P}(\mathcal{L})$ can be seen as a symmetric matrix whose entries are linear forms in two variables, that is, a vector bundle map on $\mathbb{P}^1 = \mathbb{P}(\mathcal{L})$ of the form $V^* \otimes \mathcal{O}_{\mathbb{P}^1}(-1) \rightarrow V \otimes \mathcal{O}_{\mathbb{P}^1}$, inducing a long exact sequence:

$$0 \rightarrow E^*(-1) \rightarrow V^* \otimes \mathcal{O}_{\mathbb{P}^1}(-1) \rightarrow V \otimes \mathcal{O}_{\mathbb{P}^1} \rightarrow E \rightarrow 0. \quad (1)$$

The cokernel is a vector bundle of rank $N+1-k$ on \mathbb{P}^1 , hence it splits as a direct sum of line bundles; we denote it by E . The symmetry implies that the kernel is $E^*(-1)$.

From a direct computation of invariants (see [10] for details), one finds that the rank $k = 2r$ is even, the bundle E is generated by its global sections, and moreover its first Chern class is $c_1(E) = r$.

We start our description of \mathcal{L} generalizing to the symmetric case some results from [7] that refer to the skew-symmetric case. We are of course interested in non-trivial cases: for this, recall that a space of matrices is called *non-degenerate* if the kernels of its elements intersect in the zero subspace and the images of its elements generate the entire vector space V . This is equivalent to saying that the space is not $\mathrm{GL}(N+1)$ -equivalent to a space of matrices with a row or a column of zeroes. Therefore the classification of degenerate spaces of matrices can be traced back to that of non-degenerate spaces of matrices of smaller size. From now on, we will only consider non-degenerate spaces of constant rank $2r$.

Non-degeneracy also implies that as the quadrics vary in the pencil \mathcal{L} , their vertices are pairwise disjoint.

An immediate remark is that not all values of N allow a non-degenerate pencil of symmetric matrices of size $N+1$ and fixed constant rank $2r$.

PROPOSITION 2.1. *Let $\mathcal{L} \subset \mathbb{P}(S^2V)$ be a non-degenerate pencil of singular quadrics of constant rank $2r$. Then $2r \leq N \leq 3r - 1$.*

Proof. The proof of [7, Proposition 3.6] goes through step by step. Since the cokernel bundle E from (1) is a vector bundle on \mathbb{P}^1 , it is of the form

$$E = \mathcal{O}_{\mathbb{P}^1}^{m_0} \oplus \mathcal{O}_{\mathbb{P}^1}(1)^{m_1} \oplus \cdots \oplus \mathcal{O}_{\mathbb{P}^1}(k)^{m_k},$$

where m_0, \dots, m_k are non-negative integers such that $m_1 + 2m_2 + \dots + km_k = c_1(E) = r$, and $m_0 + m_1 + \dots + m_k = \text{rk}(E) = N + 1 - 2r$.

The assumption that \mathcal{L} is non-degenerate implies $m_0 = 0$.

Obviously $2r \leq N$. For the other inequality, notice that

$$r = m_1 + 2m_2 + \dots + km_k = (m_1 + m_2 + \dots + m_k) + (m_2 + 2m_3 + \dots + (k-1)m_k);$$

since $m_0 = 0$, $m_1 + m_2 + \dots + m_k = N + 1 - 2r$, while since $k \geq 1$, $m_2 + 2m_3 + \dots + (k-1)m_k \geq 0$. This means that $r \geq N + 1 - 2r$, and thus $3r - 1 \geq N$. \square

The group $GL(N+1)$ acts by congruence on $\mathbb{P}(S^2V)$, the space of quadrics in $\mathbb{P}(V)$, and thus it acts on pencils of quadrics, that correspond to lines in $\mathbb{P}(S^2V)$: this induces an action on the Grassmannian $\mathbb{G}(1, \mathbb{P}(S^2V))$. Given a non-degenerate pencil of quadrics in $\mathbb{P}(V)$, the splitting type of the vector bundle E determines a partition of the integer r in h parts, where the number of parts $h = N + 1 - 2r$ is exactly the rank of the bundle E . For every choice of constant rank $2r$ there are exactly r possible sizes $N + 1$ for these pencils, namely N can vary from $2r$ to $3r - 1$. On the other hand, if the rank and the order of the matrix are fixed, the number of parts h of the partition of r is determined.

Our main result in this Section states that, for a fixed r , all possible values of N are attained, and that the partitions of r consisting of $h = N + 1 - 2r$ parts completely characterize the orbits of pencils of quadrics of constant rank.

In our proof we will use the classification of the $GL(N+1)$ -orbits given in terms of minimal indices, see [9, Chapter XII, §6].

In fact, even if $GL(N+1)$ acts on a pencil $\mathcal{L} \subset \mathbb{P}(S^2V)$ by congruence, one can also consider a different natural action of the general linear group on \mathcal{L} , namely two pencils of matrices $aA + bB$ and $\lambda L + \mu M$ are called *strictly equivalent* if there exist two non-singular matrices P' and P'' with the property that $P'(aA + bB)P'' = \lambda L + \mu M$. The latter action implies the former if the matrices are symmetric or skew-symmetric [9, Theorem 6, Chapter XII]: in particular, two pencils of quadrics are strictly equivalent if and only if they are congruent.

Following the same notations as [9] (so slightly different than [7]), our construction is based on the following “building blocks”.

DEFINITION 2.2. *Let $r \geq 1$ be an integer, and (r_1, \dots, r_h) a partition of r , with $r_1 \leq \dots \leq r_h$. Set $N = 2r + h - 1$. Denote by $\mathcal{L}_{(r_1, \dots, r_h)}$ the pencil*

of $(N + 1) \times (N + 1)$ symmetric matrices of constant rank $2r$ constructed as follows.

First, define the $r_i \times (r_i + 1)$ matrix

$$M_{r_i} := \begin{pmatrix} a & b & 0 & 0 & \cdots & 0 \\ 0 & a & b & 0 & \cdots & 0 \\ \vdots & & \ddots & \ddots & & \vdots \\ 0 & \cdots & & 0 & a & b \end{pmatrix}, \quad (2)$$

and the $(2r_i + 1) \times (2r_i + 1)$ symmetric block matrix

$$\mathcal{L}_{r_i} := \begin{pmatrix} 0_{r_i, r_i} & M_{r_i} \\ {}^t M_{r_i} & 0_{r_i+1, r_i+1} \end{pmatrix}. \quad (3)$$

The pencil of quadrics $\mathcal{L}_{(r_1, \dots, r_h)}$ is the direct sum of the blocks \mathcal{L}_{r_i} , so

$$\mathcal{L}_{(r_1, \dots, r_h)} := \begin{pmatrix} \mathcal{L}_{r_1} & & & \\ & \mathcal{L}_{r_2} & & \\ & & \ddots & \\ & & & \mathcal{L}_{r_h} \end{pmatrix}, \quad (4)$$

where all off-diagonal blank spaces are blocks of zeros.

By combining the construction of the pencils $\mathcal{L}_{(r_1, \dots, r_h)}$ and the classification contained in Theorem 7 and the subsequent remarks in [9, Chapter XII, §6], we obtain the following Theorem, that achieves a complete description of the $\mathrm{GL}(N + 1)$ -orbits of singular pencils of quadrics $\mathcal{L} \subset \mathbb{P}(S^2V)$ of constant rank.

THEOREM 2.3. *Let V be a complex vector space of dimension $N + 1$, and let $\mathcal{L} \subseteq \mathbb{P}(S^2V)$ be a singular pencil of quadrics of constant rank $2r$. If \mathcal{L} is non-degenerate, it is $\mathrm{GL}(N + 1)$ -equivalent by congruence and strict equivalence to a pencil of type $\mathcal{L}_{(r_1, \dots, r_h)}$ defined in (4) for some partition (r_1, \dots, r_h) of r , with $r_1 \leq \dots \leq r_h$, $h = N + 1 - 2r$, and whose associated vector bundle E has splitting type precisely (r_1, \dots, r_h) .*

Viceversa, for every integer $r \geq 1$ and every partition (r_1, \dots, r_h) of r , with $r_1 \leq \dots \leq r_h$, there exists a non-degenerate singular pencil of quadrics of constant rank $2r$ and size $N + 1$, for all $2r \leq N \leq 3r - 1$.

REMARK 2.4. An alternative proof of Theorem 2.3 could be obtained by adapting to the symmetric case the proof of [7, Theorem 3.12], which is based on compression spaces and 1-generic matrices.

REMARK 2.5. If one wanted to take into consideration degenerate pencils, it would be enough to consider partitions of r that admit 0 as a summand, with multiplicity corresponding to the number of copies of $\mathcal{O}_{\mathbb{P}^1}$ appearing in the splitting of the vector bundle E in (1).

To conclude this Section, we underline the fact that the content of Theorem 2.3 was already known, even though the relation between the classification of the orbits of singular pencils of quadrics of constant rank and the splitting type of the vector bundle has never been explicitly written down. In [3] the Author provides a geometric classification of the orbits, but the relation with the vector bundles is not clarified; on the other hand, in the recent work [6] there is an explicit description of the splitting type of the bundles, but the Authors are interested in different properties than the orbits of pencils in the Grassmannian.

3. Geometry of pencils of quadrics and their orbits

We now want to study more in detail the geometry of pencils of quadrics of constant rank and their orbits. To this end, in this Section we use a different canonical form from the one given in Definition 2.2 for the pencils with $h \geq 2$. It is analogous to the canonical form described in [7] in the skew-symmetric case, and is more convenient to understand the geometry of our pencils because it highlights that they are compression spaces. Recall that a subspace \mathcal{L} contained in $V \otimes V$ is called a *compression space* if there exists a subspace $U \subseteq V$ that is “compressed” by the elements of \mathcal{L} , that is, $\dim(L(U)) < \dim(U)$ for all $L \in \mathcal{L}$. Such a space is $GL(N+1)$ -equivalent to a space of matrices having a common block of zeros.

We start by describing some examples, namely the first cases where $r = 1, 2$ and 3.

EXAMPLE 3.1. The first (and easiest) example is $r = 1$: then the only possible value for N is 2, and the only partition of r is (1), so there is a unique orbit, whose representative is the compression space

$$\mathcal{L}_{(1)} = \left(\begin{array}{c|cc} 0 & a & b \\ \hline a & & \\ b & & 0_{2,2} \end{array} \right). \quad (5)$$

The cokernel bundle from the exact sequence (1) is $E = \mathcal{O}_{\mathbb{P}^1}(1)$. This is a pencil of conics in \mathbb{P}^2 , generated by $A = \{x_0x_1 = 0\}$ and $B = \{x_0x_2 = 0\}$, that split into a common line $S = \{x_0 = 0\}$ and a second line that goes through the point $P = [1 : 0 : 0]$. The base locus of the pencil is exactly the union of the line S , and the isolated point P . Notice that S is swept by the singular points of the conics of the pencil.

The pencils belonging to the orbit of $\mathcal{L}_{(1)}$ in the Grassmannian $\mathbb{G}(1, \mathbb{P}^5)$ are determined by their base locus, that varies in the open subset of $\mathbb{P}^2 \times \mathbb{P}^{2*}$ of disjoint pairs point-line. Therefore the orbit in $\mathbb{G}(1, \mathbb{P}^5)$ has dimension 4.

EXAMPLE 3.2. When $r = 2$, the possible values of N are 4 and 5, corresponding to the two partitions (2) and (1, 1).

The first case gives a 5×5 symmetric matrix of constant rank 4:

$$\mathcal{L}_{(2)} = \left(\begin{array}{cc|ccc} & & & a & b & 0 \\ & 0_{2,2} & & 0 & a & b \\ \hline a & 0 & & & & \\ b & a & & & 0_{3,3} & \\ 0 & b & & & & \end{array} \right),$$

with associated line bundle $\mathcal{O}_{\mathbb{P}^1}(2)$. The pencil is generated by the quadrics $A = \{x_0x_2 + x_1x_3 = 0\}$ and $B = \{x_0x_3 + x_1x_4 = 0\}$; its elements are cones over quadrics in \mathbb{P}^3 , having a single point as vertex. As the cones vary, their vertices describe a conic Γ in the plane $S = \{x_0 = x_1 = 0\}$. The base locus is the union of the plane S and the rational normal scroll of degree 3 in \mathbb{P}^4 defined by the 2×2 minors of the matrix

$$\begin{pmatrix} x_0 & x_3 & x_4 \\ -x_1 & x_2 & x_3 \end{pmatrix}.$$

The singular locus of the base locus is the conic Γ , which coincides with the improper intersection of the 2 irreducible components.

A pencil in this orbit is completely determined by its base locus, that is the union of a rational normal scroll and a plane generated by a unisecant conic. From [5] we learn that the Hilbert scheme of these rational normal scrolls has dimension 12; moreover the linear system of unisecant conics on such a surface has dimension 2; it follows that the orbit has dimension 14.

The partition (1, 1) of $r = 2$ gives a 6×6 symmetric matrix of constant rank 4, whose associated bundle is $E = \mathcal{O}_{\mathbb{P}^1}(1) \oplus \mathcal{O}_{\mathbb{P}^1}(1)$. As we mentioned at the beginning of the Section, we consider the following canonical form (here and in the next examples the blank spaces all represent zeros):

$$\tilde{\mathcal{L}}_{(1,1)} = \left(\begin{array}{cc|cccc} & & & a & b & 0 & 0 \\ & & & 0 & 0 & a & b \\ \hline a & 0 & & & & & \\ b & 0 & & & & & \\ 0 & a & & & & & \\ 0 & b & & & & & \end{array} \right).$$

Of course, $\tilde{\mathcal{L}}_{(1,1)}$ is strictly equivalent to the block construction from Defini-

tion 2.2, namely:

$$\mathcal{L}_{(1,1)} = \left(\frac{\mathcal{L}_1}{\mathcal{L}_1} \right).$$

Since the co-rank is 2, the cones of this pencil have a line as vertex. The generators are $A = \{x_0x_2 + x_1x_4 = 0\}$ and $B = \{x_0x_3 + x_1x_5 = 0\}$, the base locus is reducible, and its components are the 3-dimensional linear space $S = \{x_0 = x_1 = 0\}$ and a rational normal 3-fold scroll of degree 3 in \mathbb{P}^5 , defined by the 2×2 minors of

$$\begin{pmatrix} x_0 & x_4 & x_5 \\ -x_1 & x_2 & x_3 \end{pmatrix}.$$

The locus swept by vertices is a smooth quadric surface in S . By a count of parameters similar to previous case, the dimension of the orbit is 26: indeed, the dimension of the Hilbert scheme of rational normal cubic scrolls in \mathbb{P}^5 is 24 and the linear system of unisecant quadrics has dimension 2.

One of the advantages of using the form $\tilde{\mathcal{L}}_{(1,1)}$ lies precisely in the fact that the codimension 2 linear space S contained in the base locus is now apparent, since we are dealing with a compression space. This phenomenon will generalize in the next cases.

EXAMPLE 3.3. As a last series of examples, aiming to illustrate the general case, we now consider the possible partitions of $r = 3$. One has three possible values $6 \leq N \leq 8$, corresponding to the three partitions (3), (1, 2) and (1, 1, 1). By now we know that the representatives of their orbits are, respectively,

$$\mathcal{L}_{(3)} = \left(\begin{array}{ccc|ccc} & & & a & b & 0 & 0 \\ & 0_{3,3} & & 0 & a & b & 0 \\ & & & 0 & 0 & a & b \\ \hline a & 0 & 0 & & & & \\ b & a & 0 & & & & \\ 0 & b & a & & 0_{4,4} & & \\ 0 & 0 & b & & & & \end{array} \right), \quad \mathcal{L}_{(1,2)}, \quad \text{and} \quad \mathcal{L}_{(1,1,1)}.$$

The base locus of the pencil $\mathcal{L}_{(3)}$ in \mathbb{P}^6 is an irreducible quartic, complete intersection of the two quadrics $A = \{x_0x_3 + x_1x_4 + x_2x_5 = 0\}$ and $B = \{x_0x_4 + x_1x_5 + x_2x_6 = 0\}$; it is singular along a twisted cubic C swept by the vertices and it contains the 3-dimensional linear space $S = \{x_0 = x_1 = x_2 = 0\}$ spanned by C .

To analyze the other two cases, we will again look at representatives that

are strictly equivalent to $\mathcal{L}_{(1,2)}$ and $\mathcal{L}_{(1,1,1)}$, namely:

$$\tilde{\mathcal{L}}_{(1,2)} = \left(\begin{array}{ccc|ccccc} & & & a & b & 0 & 0 & 0 & 0 \\ & & & 0 & 0 & a & b & 0 & 0 \\ & & & 0 & 0 & 0 & a & b & 0 \\ \hline a & 0 & 0 & & & & & & \\ b & 0 & 0 & & & & & & \\ 0 & a & 0 & & & & & & \\ 0 & b & a & & & & & & \\ 0 & 0 & b & & & & & & \end{array} \right)$$

and

$$\tilde{\mathcal{L}}_{(1,1,1)} = \left(\begin{array}{ccc|cccccc} & & & a & b & 0 & 0 & 0 & 0 & 0 \\ & & & 0 & 0 & a & b & 0 & 0 & 0 \\ & & & 0 & 0 & 0 & 0 & a & b & 0 \\ \hline a & 0 & 0 & & & & & & & \\ b & 0 & 0 & & & & & & & \\ 0 & a & 0 & & & & & & & \\ 0 & b & 0 & & & & & & & \\ 0 & 0 & a & & & & & & & \\ 0 & 0 & b & & & & & & & \end{array} \right).$$

Considering the kernels of these matrices, we see that in both cases the Jacobian locus of the pencil is contained in the linear space $S = \{x_0 = x_1 = x_2 = 0\}$ of codimension 3 (so of dimension 4 and 5 respectively). The base locus is irreducible in both cases and it is singular along the Jacobian locus, that is a rational normal scroll in S , $\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(1) \oplus \mathcal{O}_{\mathbb{P}^1}(2))$ and $\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(1) \oplus \mathcal{O}_{\mathbb{P}^1}(1) \oplus \mathcal{O}_{\mathbb{P}^1}(1))$ respectively.

We now describe the general case of a pencil $\mathcal{L} = \mathcal{L}_{(r_1, \dots, r_h)}$ of constant rank $2r$ in \mathbb{P}^N , corresponding to the partition (r_1, \dots, r_h) of r , $h = N + 1 - 2r$. Recall that we can write our \mathcal{L} as $\{aA + bB \mid [a : b] \in \mathbb{P}^1\}$. We denote by $B(\mathcal{L}) = A \cap B$ the base locus of \mathcal{L} . It is a known fact that its singular locus is contained in the Jacobian locus $J(\mathcal{L})$ of \mathcal{L} , the union of the vertices of the quadrics in the pencil, and such vertices are linear spaces of dimension $N - 2r$.

As we did in the previous examples, we use a canonical form for the pencils that is slightly different from (4), and instead agrees with the notations used

in [7]: given the $r_i \times (r_i + 1)$ block M_{r_i} defined in (2), we set

$$\tilde{\mathcal{L}}_{(r_1, \dots, r_h)} := \left(\begin{array}{c|cccc} & & & & M_{r_1} \\ & & & & \hline & & & & M_{r_2} \\ & & & & \hline & & & \ddots & \\ & & & & \hline & & & & M_{r_h} \\ \hline {}^t M_{r_1} & & & & \\ \hline & {}^t M_{r_2} & & & \\ \hline & & \ddots & & \\ \hline & & & {}^t M_{r_h} & \end{array} \right), \quad (6)$$

where again the blank spaces have blocks of zeros.

From this canonical form, it is immediate to see that all these pencils correspond to compression spaces, because the associated matrices have a block of zeros of dimension $N + 1 - r$; a direct consequence is that the Jacobian locus $J(\mathcal{L})$ is contained in the linear space S of dimension $N - r$ defined by the equations $x_0 = x_1 = \dots = x_{r-1} = 0$.

Moreover, one easily computes that the Jacobian locus coincides with the singular locus of $B(\mathcal{L})$, which is irreducible, and it is exactly a rational normal scroll $\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(r_1) \oplus \dots \oplus \mathcal{O}_{\mathbb{P}^1}(r_h))$. Any element of the pencil is a cone over a smooth quadric of dimension $2r - 2$, so it admits two families of linear spaces of dimension $(r - 1) + (N - 2r) + 1 = N - r$. Two quadrics of the pencil share a maximal linear subspace S of dimension $N - r$ belonging to one of the two families, and are tangent along a rational normal scroll of type r_1, \dots, r_h in S .

As a last remark ending this Section, we quote the article [13], a continuation and completion of the thesis of Corrado Segre, where he studied the geometry of singular pencils of quadrics in \mathbb{P}^N of rank at most k , that he calls “coni quadrici di specie $N - k$ ”, relating them to rational normal scrolls contained in their Jacobian locus.

4. Orbits' dimension

We recalled in Section 2 that the natural action of the group $\mathrm{GL}(N + 1)$ on $V = \mathbb{C}^{N+1}$ extends to the congruence action on $\mathbb{P}(S^2V)$, and hence on the lines contained in $\mathbb{P}(S^2V)$. Looking at pencils of quadrics as points in the Grassmannian $\mathbb{G}(1, \mathbb{P}(S^2V))$, we get an action of $\mathrm{GL}(N + 1)$ on the Grassmannian. We are interested in the orbits of singular pencils of quadrics $\mathcal{L} \subseteq \mathbb{P}(S^2V)$ of constant rank $2r$ under this latter action. As we saw in Theorem 2.3 non-degenerate pencils of quadrics in \mathbb{P}^N of constant rank $2r$ exist if and only if

$2r \leq N \leq 3r - 1$ and the orbits of these pencils correspond bijectively to the partitions (r_1, \dots, r_h) of r , with $1 \leq r_1 \leq r_2 \leq \dots \leq r_h$, where $h = N + 1 - 2r$.

This last Section contains our main result Theorem 4.1, namely we compute the dimension of all the orbits of pencils of singular quadrics of constant rank. More precisely, for every partition (r_1, \dots, r_h) we describe explicitly the Lie algebra of the stabilizer of the pencil $\mathcal{L}_{(r_1, \dots, r_h)}$.

THEOREM 4.1. *Let $r \geq 1$ be an integer, and (r_1, \dots, r_h) a partition of r , with $r_1 \leq \dots \leq r_h$. Set $N = 2r + h - 1$. Under the natural action of $\mathrm{GL}(N + 1)$, the dimension of the stabilizer of the singular pencil $\mathcal{L}_{(r_1, \dots, r_h)}$ of symmetric matrices of size $N + 1$ and constant rank $2r$ is*

$$\delta(r_1, \dots, r_h) := h + 4 + \sum_{i < j} (2r_j + 1) + \#\{(i, j) \mid r_i = r_j\}. \quad (7)$$

COROLLARY 4.2. *The $\mathrm{GL}(N + 1)$ -orbits of singular pencils $\mathcal{L}_{(r_1, \dots, r_h)}$ of symmetric matrices of size $N + 1$ and constant rank $2r$ have (affine) dimension $(N + 1)^2 - \delta(r_1, \dots, r_h)$.*

The plan of the proof of Theorem 4.1 is the following: we first analyze, in Propositions 4.5 and 4.6 the case of partitions with only one part, i.e. pencils of symmetric matrices of constant corank 1; then, in Proposition 4.7, we consider the case of partitions with two parts, i.e. pencils of constant corank 2. We obtain a complete description of the Lie algebra of the stabilizer in both cases. The key remark is then that, in the general case, due to the particular canonical form of the representatives of the orbits under consideration, a matrix X in the Lie algebra of the stabilizer can be interpreted as a block matrix of the form (16), where the blocks involved already appear and are described in the first two cases.

The next Lemma is probably well known. We report it here for completeness and because it is a fundamental ingredient for computing the Lie algebras of the stabilizers in the two cases $h = 1, 2$.

LEMMA 4.3. *Let \mathcal{L} be the pencil generated by the symmetric matrices A and B , let X be a $(N + 1) \times (N + 1)$ matrix with entries in \mathbb{C} . Then X belongs to the Lie algebra of the stabilizer of \mathcal{L} for the action of $\mathrm{GL}(N + 1)$ on the Grassmannian if and only if the following relations hold:*

$$({}^tXA + AX) \wedge A \wedge B = ({}^tXB + BX) \wedge A \wedge B = 0. \quad (8)$$

Proof. The point in the Grassmannian $\mathbb{G}(1, \mathbb{P}(S^2V))$ corresponding to the pencil \mathcal{L} via the Plücker map is $[A \wedge B]$. Its $\mathrm{GL}(N + 1)$ -orbit is the image of the map $\mathrm{GL}(N + 1) \rightarrow \mathbb{G}(1, \mathbb{P}(S^2V))$ given by $X \mapsto ({}^tXAX) \wedge ({}^tXBX)$. So the condition for X to belong to the stabilizer of \mathcal{L} is $[A \wedge B] = [({}^tXAX) \wedge ({}^tXBX)]$. This is equivalent to the equations $({}^tXAX) \wedge A \wedge B = ({}^tXBX) \wedge A \wedge B = 0$. Differentiating these equations at the origin we get the thesis. \square

Now, using (11) and (12) together with (i) we get $x_{0,r} = x_{1,r+1} = \cdots = x_{r-1,2r-1} = x_{r,0} = \cdots = x_{2r-1,r-1} = 0$, and also $x_{0,r+1} = x_{1,r+2} = \cdots = x_{r-2,2r-1} = x_{r+1,0} = \cdots = x_{2r,r-1} = 0$; note that in all these cases the difference of the indices is either r or $r+1$.

From the vanishings just obtained and those in (ii) whose indices differ by 1, we get $x_{0,r-1} = x_{1,r} = \cdots = x_{r-1,2r-2} = x_{r-1,0} = \cdots = x_{2r-2,r-1} = 0$, $x_{0,r+2} = x_{1,r+3} = \cdots = x_{r-2,2r} = x_{r+2,0} = \cdots = x_{2r,r-2} = 0$, and also $x_{2r,r} = x_{r-1,2r} = 0$.

We continue in this way, considering relations in (ii) whose indices differ by 2 and so on, until we get all the claimed vanishings in matrix (10) and moreover the following $2r$ equations:

$$x_{0,1} + x_{r+1,r} = x_{1,2} + x_{r+2,r+1} = \cdots = x_{r-1,r} + x_{2r,2r-1} = 0,$$

and the symmetric ones

$$x_{1,0} + x_{r,r+1} = x_{2,1} + x_{r+1,r+2} = \cdots = x_{r,r-1} + x_{2r-1,2r} = 0.$$

The relations in (iii) and (iv) impose $2r-2$ conditions on the elements of the main diagonal of X , and $2r-2$ conditions on the elements of the subdiagonal and supradiagonal of X , and precisely:

$$x_{0,0} + x_{r,r} = x_{1,1} + x_{r+1,r+1} = \cdots = x_{r-1,r-1} + x_{2r-1,2r-1},$$

$$x_{0,0} + x_{r+1,r+1} = x_{1,1} + x_{r+2,r+2} = \cdots = x_{r-1,r-1} + x_{2r,2r},$$

$$x_{1,0} + x_{r,r+1} = x_{2,1} + x_{r+1,r+2} = \cdots = x_{2r-1,2r},$$

$$x_{r+1,r} = x_{0,1} + x_{r+2,r+1} = \cdots = x_{r-2,r-1} + x_{2r,2r-1}.$$

Combining everything, we obtain for X the expression in (10), with $z = x_{0,1}$ and $y = x_{r-1,r-2}$; the Proposition is proved. \square

Our description of the stabilizer compared with the known classification of Lie algebras of small dimension ([11]) gives the following result.

PROPOSITION 4.6. *The Lie algebra of the stabilizer of the $\mathrm{GL}(2r+1)$ -orbit of pencils of quadrics of constant rank $2r$ and order $2r+1$ described in Proposition 4.5 is isomorphic to $\mathfrak{sl}_2 \times \mathbb{C}^2$.*

Proof. From the detailed description of the Lie algebra of the stabilizer given in Proposition 4.5, one sees that its elements depend on 5 independent parameters, namely any element X in this Lie algebra is $X = X(x_{00}, x_{11}, x_{33}, y, z)$. With obvious notation, let us call

$$\mathcal{C}_1 = X(1, 0, 0, 0, 0), \quad \mathcal{C}_2 = X(0, 1, 0, 0, 0),$$

$$\mathcal{X} = X(0, 0, 0, 0, 1), \quad \mathcal{Y} = X(0, 0, 0, 1, 0), \quad \mathcal{Z} = X(r-1, r-3, -r, 0, 0).$$

If we compute the bracket of these elements, we get that $[\mathcal{C}_1, \mathcal{C}_2] = 0$ and

$$\begin{cases} [\mathcal{X}, \mathcal{Y}] = \mathcal{Z} \\ [\mathcal{Z}, \mathcal{X}] = 2\mathcal{X} \\ [\mathcal{Z}, \mathcal{Y}] = -2\mathcal{Y} \end{cases}$$

which tells us that $\mathbb{C}^2 = \langle \mathcal{C}_1, \mathcal{C}_2 \rangle$ and $\mathfrak{sl}_2 = \langle \mathcal{X}, \mathcal{Y}, \mathcal{Z} \rangle$. The fact that

$$\begin{cases} [\mathcal{C}_1, \mathcal{X}] = \mathcal{X} = -[\mathcal{C}_2, \mathcal{X}] \\ [\mathcal{C}_1, \mathcal{Y}] = -\mathcal{Y} = -[\mathcal{C}_2, \mathcal{Y}] \\ [\mathcal{C}_1, \mathcal{Z}] = [\mathcal{C}_2, \mathcal{Z}] = 0 \end{cases}$$

allows us to conclude that our Lie algebra falls into the first case in the classification table appearing in [11, Section 4], namely the semidirect product $\mathfrak{sl}_2 \ltimes \mathbb{C}^2$. \square

When the partition has $h = 2$ parts, the balanced and unbalanced case have two different behaviors, as explained in the following result.

PROPOSITION 4.7. *Let $r \geq 1$ be an integer. The $\mathrm{GL}(2r + 2)$ -orbit of pencils of singular quadrics of constant rank $2r$ and order $2r + 2$, whose associated bundle is $\mathcal{O}_{\mathbb{P}^1}(r_1) \oplus \mathcal{O}_{\mathbb{P}^1}(r_2)$, with $r_1 + r_2 = r$, and $r_1 \leq r_2$, has stabilizer of dimension*

1. $2r_2 + 8 = r + 8$ when r is even and $r_1 = r_2 = \frac{r}{2}$;
2. $2r_2 + 7$ when $r_1 < r_2$.

Proof. In the notation of Section 2, a representative of the orbit is the matrix

$$\mathcal{L}_{(r_1, r_2)} = aA + bB = \left(\begin{array}{c|c} \mathcal{L}_{r_1} & \\ \hline & \mathcal{L}_{r_2} \end{array} \right).$$

We also introduce the notation $A = \left(\begin{array}{c|c} A_1 & \\ \hline & A_2 \end{array} \right)$, $B = \left(\begin{array}{c|c} B_1 & \\ \hline & B_2 \end{array} \right)$, where A_i, B_i are matrices of order $2r_i + 1$, for $i = 1, 2$.

Let $X = (x_{ij})_{i,j=0,\dots,N}$ be a matrix of unknowns. We write X as a block matrix as follows:

$$X = \left(\begin{array}{c|c} X_{11} & X_{12} \\ \hline X_{21} & X_{22} \end{array} \right) = \left(\begin{array}{c|c} (x_{ij})_{\substack{i=0,\dots,2r_1+1 \\ j=0,\dots,2r_1+1}} & (x_{ij})_{\substack{i=0,\dots,2r_1+1 \\ j=2r_1+2,\dots,N}} \\ \hline (x_{ij})_{\substack{i=2r_1+2,\dots,N \\ j=0,\dots,2r_1+1}} & (x_{ij})_{\substack{i=2r_1+2,\dots,N \\ j=2r_1+2,\dots,N}} \end{array} \right)$$

where X_{ii} are square matrices of order $(2r_i + 1)$, and X_{12}, X_{21} have order $(2r_1 + 1) \times (2r_2 + 1)$ and $(2r_2 + 1) \times (2r_1 + 1)$ respectively.

Then ${}^tXA + AX$ and ${}^tXB + BX$ can be written as block matrices as well, and precisely:

$${}^tXA + AX = \left(\begin{array}{c|c} {}^tX_{11}A_1 + A_1X_{11} & {}^tX_{21}A_2 + A_1X_{12} \\ \hline {}^tX_{12}A_1 + A_2X_{21} & {}^tX_{22}A_2 + A_2X_{22} \end{array} \right), \quad (13)$$

and similarly for B . Lemma 8 implies that X belongs to the Lie algebra of the stabilizer if and only if equations (8) are satisfied. We analyze separately what this means for the diagonal blocks X_{11}, X_{22} and for the off-diagonal blocks X_{12}, X_{21} of X .

Diagonal blocks. We use Proposition 4.5: X_{11}, X_{22} must belong to the Lie algebras of the stabilizers of the orbits of $\mathcal{L}_{(r_1)}$ and $\mathcal{L}_{(r_2)}$ respectively, therefore each of them depends on 5 parameters and has the form described in Proposition 4.5. But equations (8) imply that the parameters appearing in X_{11} and X_{22} are not independent, and precisely, after fixing the 5 parameters required to describe X_{11} , an explicit computation shows that only one new parameter is needed to describe X_{22} , therefore the two diagonal blocks depend on a total of 6 parameters.

Off-diagonal blocks. The matrices ${}^tX_{21}A_2 + A_1X_{12}$ and ${}^tX_{12}A_1 + A_2X_{21}$ are the transpose of each other, and they both have to be the zero matrix. The same holds for ${}^tX_{21}B_2 + B_1X_{12}$ and ${}^tX_{12}B_1 + B_2X_{21}$.

From the explicit expressions of their entries, we get the following conditions:

$$\begin{aligned} x_{a,b} + x_{i,j} &= 0 \text{ for any } 2r_1 + 1 \leq a, j \leq 2r, 0 \leq i, b \leq 2r_1 - 1 & (14) \\ &\text{with } |b - i| = r_1, |a - j| = r_2, \end{aligned}$$

$$\begin{aligned} x_{a,b} + x_{i,j} &= 0 \text{ for any } 2r_1 + 1 \leq a, j \leq 2r + 1, 0 \leq i, b \leq 2r_1 & (15) \\ &\text{with } |b - i| = r_1 + 1, |a - j| = r_2 + 1. \end{aligned}$$

We also get a first series of four vanishings, referring to the last and the central columns of X_{12} and X_{21} :

- (i) the last column of X_{12} except its last element:

$$x_{0,2r+1} = x_{1,2r+1} = \cdots = x_{2r_1-1,2r+1} = 0,$$

- (ii) the central column of X_{12} , of index $2r_1 + r_2 + 1$, except its central element $x_{r_1,2r_1+r_2+1}$;

- (iii) the last column of X_{21} except its last element:

$$x_{2r_1+1,2r_1} = x_{2r_1+2,2r_1} = \cdots = x_{2r,2r_1} = 0,$$

- (iv) the central column of X_{21} , of index r_1 , with the exception of its central element $x_{2r_1+r_2+1,r_1}$.

The vanishing of these columns, together with conditions (14) and (15), implies, in order, the following second series of vanishings, referring to the rows of the two matrices:

- (i) the row of index $2r_1 + r_2$ of X_{21} , except the element $x_{2r_1+r_2,r_1-1}$; this is the row above the middle;
- (ii) the first row of X_{21} except its first element $x_{2r_1+1,0}$;
- (iii) the row of index $r_1 - 1$ of X_{12} except $x_{r_1-1,2r_1+r_2}$; this is the row above the middle;
- (iv) the first row of X_{12} except its first element $x_{0,2r_1+1}$.

We now analyze separately the two cases (1) and (2) in our statement.

Case (1): when $r_1 = r_2$, X_{12}, X_{21} are square matrices. Going on with the argument above, we deduce that in both X_{12} and X_{21} all the elements above the central row and to the right of the central column are zero, except those of the main diagonal. Moreover, the first r_2 entries of the main diagonal of X_{12} are equal to each other and also to the last r_2 elements of the main diagonal of X_{21} , and similarly the last r_2 elements of the main diagonal of X_{12} are equal to each other and also to the first r_2 elements of the main diagonal of X_{21} .

We are left to analyze the two rectangles of order $(r_2 + 1) \times r_2$ in the lower left corner: from conditions (14) and (15) we get that they depend on $2r_2$ parameters, independent of those previously considered. More precisely, we can divide each of the two rectangles into its $2r_2$ anti-diagonals; each of them results to be formed by elements all equal to each other and to those of the same anti-diagonal of the other matrix.

All in all, there are $2 + 2r_2$ independent parameters for this case (1). For the reader's convenience, we illustrated the case (2, 2) in Figure 1.

Case (2): assume now $r_1 < r_2$. We obtain the vanishing of the entire first r_1 rows of X_{12} and of the last $r_1 + 1$ columns of X_{21} . Now we need to look at the last $r_1 + 1$ rows of X_{12} and the first r_1 columns of X_{21} . The former is divided into two blocks α_{12} and β_{12} of size $(r_1 + 1) \times r_2$ and $(r_1 + 1) \times (r_2 + 1)$ respectively, while the latter is divided into two blocks α_{21} and β_{21} of size $r_2 \times r_1$ and $(r_2 + 1) \times r_1$ respectively. All entries in each of the $r_2 + 2$ anti-diagonals of α_{12} are equal to each other, and the same is true for the $r_2 + 2$ anti-diagonals of β_{21} . Moreover, these diagonals are paired, in the sense that they depend in order exactly on the same $r_2 + 2$ parameters. Finally, the same relations hold for the $r_2 - 1$ principal diagonals of the blocks β_{12} and α_{21} , with the difference that this time all entries above and below these $r_2 - 1$ principal diagonals are

$$X_{12} = \begin{pmatrix} x_{0,5} & 0 & 0 & 0 & 0 \\ 0 & x_{1,6} & 0 & 0 & 0 \\ x_{2,5} & x_{3,6} & x_{2,7} & 0 & 0 \\ x_{3,5} & x_{3,6} & 0 & x_{3,8} & 0 \\ x_{4,5} & x_{4,6} & 0 & 0 & x_{4,9} \end{pmatrix} \quad X_{21} = \begin{pmatrix} x_{5,0} & 0 & 0 & 0 & 0 \\ 0 & x_{6,1} & 0 & 0 & 0 \\ x_{7,0} & x_{7,1} & x_{7,2} & 0 & 0 \\ x_{8,0} & x_{8,1} & 0 & x_{8,3} & 0 \\ x_{9,0} & x_{9,1} & 0 & 0 & x_{9,4} \end{pmatrix}$$

Figure 1: Structure of the submatrices X_{12} and X_{21} in an element of the Lie algebra of the stabilizer of $\mathcal{L}_{(2,2)}$: entries that are equal (up to a sign) are highlighted with the same color.

zero. (By “principal diagonal” we mean a maximal length diagonal with $r_1 + 1$ entries in β_{12} and r_1 entries in α_{21} .)

All in all, there are $(r_2 + 2) + (r_2 - 1) = 2r_2 + 1$ independent parameters for this case (2). Figure 2 illustrates the case (2, 3).

Notice that the unknowns appearing in the on and off-diagonal blocks are independent from each other: this means that we only need to add the number of independent parameters coming from the off-diagonal blocks to the 6 ones needed for the diagonal blocks. This concludes the proof in both cases. \square

Proof of Theorem 4.1. We mimic and generalize the proof of Proposition 4.7. Given a pencil $\mathcal{L}_{(r_1, \dots, r_h)}$ in the canonical form (4) and generated by A and B , with obvious notation we write

$$A = \left(\begin{array}{c|c|c|c} A_1 & & & \\ \hline & A_2 & & \\ \hline & & \ddots & \\ \hline & & & A_h \end{array} \right) \quad \text{and} \quad B = \left(\begin{array}{c|c|c|c} B_1 & & & \\ \hline & B_2 & & \\ \hline & & \ddots & \\ \hline & & & B_h \end{array} \right).$$

To describe the matrices X belonging to the Lie algebra of the stabilizer of $\mathcal{L}_{(r_1, \dots, r_h)}$ we use Lemma 4.3. We write a general matrix of unknowns $X = (x_{ij})_{i,j=0, \dots, N}$ as a block matrix with the same type of blocks X_{ij} as above, each of size $(2r_i + 1) \times (2r_j + 1)$:

$$X = \left(\begin{array}{c|c|c|c} X_{11} & X_{12} & \dots & X_{1h} \\ \hline X_{21} & X_{22} & & \vdots \\ \hline \vdots & & \ddots & \vdots \\ \hline X_{1h} & \dots & \dots & X_{hh} \end{array} \right). \quad (16)$$

$$X_{12} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \hline x_{2,5} & x_{3,6} & x_{2,7} & x_{2,8} & x_{2,9} & 0 & 0 \\ x_{3,5} & x_{3,6} & x_{3,7} & 0 & x_{3,9} & x_{3,10} & 0 \\ x_{4,5} & x_{4,6} & x_{4,7} & 0 & 0 & x_{4,10} & x_{4,11} \end{pmatrix} \quad X_{21} = \begin{pmatrix} x_{5,0} & 0 & 0 & 0 & 0 \\ x_{6,0} & x_{6,1} & 0 & 0 & 0 \\ 0 & x_{7,1} & 0 & 0 & 0 \\ \hline x_{8,0} & x_{8,1} & 0 & 0 & 0 \\ x_{9,0} & x_{9,1} & 0 & 0 & 0 \\ x_{10,0} & x_{10,1} & 0 & 0 & 0 \\ x_{11,0} & x_{11,1} & 0 & 0 & 0 \end{pmatrix}$$

Figure 2: Structure of the submatrices X_{12} and X_{21} in an element of the Lie algebra of the stabilizer of $\mathcal{L}_{(2,3)}$: again, the entries that are equal (up to a sign) are highlighted with the same color.

Then ${}^tXA + AX$ can also be written as a block matrix, where the square blocks on the diagonal have the form

$${}^tX_{ii}A_i + A_iX_{ii},$$

while the off-diagonal ones with $i < j$ are

$${}^tX_{ji}A_j + A_iX_{ij},$$

and similarly for B . As in the proof of Proposition 4.7, the upper left diagonal block X_{11} depends on 5 independent parameters, and each other diagonal block contributes with 1 more degree of freedom. This accounts for $5 + (h-1) = 4 + h$ parameters. The off-diagonal blocks X_{ij} and its symmetric X_{ji} are in the same relation described for X_{12} and X_{21} in the proof of Proposition 4.7, so each pair accounts for $2r_j + 2$ if $r_i = r_j$, and $2r_j + 1$ if $r_i < r_j$.

As anticipated, now we make the key remark that the blocks X_{ij} and $X_{k\ell}$ are independent for $(i, j) \neq (k, \ell)$, meaning that none of the variables x_{pq} appear in two different blocks; therefore, the total number of parameters is

$$4 + h + \sum_{i < j} (2r_j + 1) + \#\{(i, j) \mid r_i = r_j\},$$

and this concludes our proof. \square

To illustrate our result, we collected in Table 1 all orbits of pencils of quadrics of constant rank $2r$, $r \leq 6$, their dimension, and the dimension of their stabilizer.

r	h	partition	$N = 2r + h - 1$	dim orbit	dim stabilizer
1	1	(1)	2	4	5
2	1	(2)	4	20	5
	2	(1,1)	5	26	10

	6	(1,1,1,1,1,1)	17	254	70

Table 1: Dimension of orbits of pencils of quadrics and their stabilizers.

Looking at Table 1, it is interesting to observe the phenomenon occurring when there are two different partitions of r of the same length. As expected from the behaviour of a rational normal scroll $\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(r_1) \oplus \mathcal{O}_{\mathbb{P}^1}(r_2))$ degenerating to a $\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(r_1 - 1) \oplus \mathcal{O}_{\mathbb{P}^1}(r_2 + 1))$, the dimension of the relative orbit increases.
