## Abstract

The classical Pell equation can be extended to the cubic case considering the elements of norm one in  $\mathbb{Z}[\sqrt[3]{r}]$ , which satisfy

$$x^3 + ry^3 + r^2z^3 - 3rxyz = 1.$$

The solution of the cubic Pell equation is harder than the classical case, indeed a method for solving it as Diophantine equation is still missing [2]. In this paper, we study the cubic Pell equation over finite fields, extending the results that hold for the classical one. In particular, we provide a novel method for counting the number of solutions in all possible cases depending on the value of  $r$ . Moreover, we are also able to provide a method for generating all the solutions.

## 1 Introduction

The Pell equation

$$x^2 - dy^2 = 1,$$

is an important and well studied Diophantine equation, for  $d$  a non-square positive integer. Finding its solutions is equivalent to finding the elements of  $\mathbb{Z}[\sqrt{d}]$  of norm one. There are well known methods for solving this equation. They are mainly based on continued fractions that allow to find a fundamental solution, which is then used for generating all the other ones. Currently, there are still several important issues regarding the Pell equation. For instance, the study of the size of the fundamental solution is an interesting problem addressed in several papers, e.g., [7, 11, 22]. Recently, the solvability of simultaneous Pell equations and explicit formulas for their solutions have been also studied in [14, 8, 12]. Moreover, it is also interesting to study the Pell equation over finite fields, determining the number of solutions and their properties [18, 20, 19, 9]. For further information about the importance of the study of the Pell equation see, e.g., [16].

Thus, it is natural to consider generalizations of the Pell equation, starting from the cubic case. Considering the connection between the Pell equation and the elements of norm one in a quadratic field, the analogue of the Pell equation in the cubic case is given by the equation

$$x^3 + ry^3 + r^2z^3 - 3rxyz = 1,$$

where  $r$  is a cube-free integer, i.e., we are asking for the elements of norm one in  $\mathbb{Z}[\sqrt[3]{r}]$ . First studies of the cubic Pell equation can be found in [17] and [21]. In [10], the author proposed a method for solving the cubic Pell equation by means of a generalization of continued fractions due to Jacobi [15]. However, this method is not always useful for this purpose, since the periodicity of the Jacobi algorithm is still a fascinating open problem for all cubic irrationals. This question was also addressed, e.g., in [5] and [6]. The solutions of the cubic Pell equation were studied in [1] from the point of view of recurrent sequences, since Lucas sequences are solutions, up to constants, of the classical Pell equation. In general, the cubic Pell equation is very hard to solve for any cube-free  $r$ . In [2], the author exhibited an algorithm for finding the fundamental solutions of the cubic Pell equation that works only in some cases. Thus, the problem of solving the cubic Pell equation is still open. For more motivation and results about the cubic Pell equation see also [13].

In this paper, we address the problem of solving the cubic Pell equation over finite fields. In particular, in Section 2 we recall the classical Pell equation and its definition as the elements of norm one in a quadratic field. We also introduce a particular parameterization, which is useful for studying the Pell equation over finite fields and it is also handy for a generalization in the cubic case. In Section 3, we recall the structure of the Pell conic over finite fields obtaining also the results of [18] in a different way. Section 4 is devoted to the introduction of the cubic Pell equation. Here, we also introduce its parameterization that will allow to study its structure over finite fields, giving also methods for generating the solutions. Finally, in Section 5, we describe the behavior of the cubic Pell equation over finite fields.

## 2 The Pell equation

The classical Pell equation is the equation of the form

$$x^2 - dy^2 = 1,$$

where  $d$  is a positive square-free integer and solutions are sought for  $(x, y) \in \mathbb{Z}^2$ .

In this work we consider the Pell equation in general terms, considering any element  $d$  in a field  $\mathbb{F}$  and taking the polynomial ring

$$\mathcal{R}_d := \mathbb{F}[t]/\langle t^2 - d \rangle$$

whose elements are the classes of equivalence

$$[x + yt] := \{x + yt + k(t)(t^2 - d) \mid k(t) \in \mathbb{F}[t]\}, \quad \text{for any } x, y \in \mathbb{F}.$$

This quotient ring inherits from the polynomial product the operation

$$[x_1 + y_1t] \cdot [x_2 + y_2t] = [(x_1x_2 + dy_1y_2) + (x_1y_2 + y_1x_2)t]. \quad (2.1)$$

The conjugate of an element  $[x + yt] \in \mathcal{R}_d$  is defined as  $[x - yt]$ . The product of an element with its conjugate defines the norm

$$N_d([x + yt]) := [x + yt] \cdot [x - yt] = x^2 - dy^2 \in \mathbb{F}.$$

The unitary elements of  $\mathcal{R}_d$  with respect to the norm  $N_d$

$$\mathcal{U}(\mathcal{R}_d) := \{[x + yt] \in \mathcal{R}_d \mid N_d([x + yt]) = 1\},$$

form a commutative group that is clearly isomorphic to the *Pell conic*

$$\mathcal{C}_d := \{(x, y) \in \mathbb{F}^2 \mid x^2 - dy^2 = 1\},$$

equipped with the classical Brahmagupta product

$$(x_1, y_1) \otimes_d (x_2, y_2) := (x_1x_2 + dy_1y_2, x_1y_2 + y_1x_2).$$

Due to this isomorphism, in the following we will use the norm  $N_d$  also for the points of the conic and the notation  $\otimes_d$  also for denoting the product over  $\mathcal{R}_d$ . In general, we denote by  $(x, y)^{\otimes_d k}$  the  $k$ -power of  $(x, y)$  with respect to  $\otimes_d$ .

The operation  $\otimes_d$  over the Pell conic has an interesting geometric interpretation [4]: in order to obtain the point  $(x_1, y_1) \otimes_d (x_2, y_2)$ , consider the line through  $(x_1, y_1), (x_2, y_2)$  and take its parallel line through  $(1, 0)$ ; the latter intersects the conic in a second point that is actually  $(x_1, y_1) \otimes_d (x_2, y_2)$ . As observed in [4], this geometric interpretation is analogous to the classical operation on elliptic curves.

In the following, we introduce a particular parametrization for the Pell conic, which is useful for studying it over finite fields and also for generalizing this study to the cubic Pell equation.

**Definition 2.1.** The *projectivization* of  $\mathcal{R}_d$  is  $\mathbb{P}_d := \mathcal{R}_d^{\otimes_d} / \mathbb{F}^\times$ , where  $\mathcal{R}_d^{\otimes_d}$  is the set of the invertible elements of  $\mathcal{R}_d$  with respect to  $\otimes_d$ . We denote the elements of  $\mathbb{P}_d$  by  $[m : n]$ . In particular, they are the classes of equivalence of the elements  $[m + nt] \in \mathcal{R}_d^{\otimes_d}$  given by

$$[m : n] := \{\lambda[m + nt] \mid \lambda \in \mathbb{F}^\times\}.$$

If  $n \in \mathbb{F}^\times$ , then  $[m + nt] \in \mathcal{R}_d^{\otimes_d}$  is equivalent to  $[mn^{-1} + t] \in \mathcal{R}_d^{\otimes_d}$ . Thus, when  $n = 0$  we choose as *canonical representative* in  $\mathbb{P}_d$   $[1 : 0]$  while, in the other cases, we take  $[mn^{-1} : 1]$ .

Since the Brahmagupta product  $\otimes_d$  consists of homogeneous polynomials, it is well defined also on  $\mathbb{P}_d$  and determines a commutative group with identity  $[1 : 0]$  and inverse of  $[m : 1]$  given by  $[-m : 1]$ .

The structure of  $\mathbb{P}_d$  depends on that of  $\mathcal{R}_d^{\otimes_d}$ :

1. if  $d$  is a non-square element in  $\mathbb{F}$ , then  $\mathcal{R}_d^{\otimes_d} = \mathcal{R}_d \setminus \{[0]\}$  and

$$\mathbb{P}_d = \{[m : 1] \mid m \in \mathbb{F}\} \cup \{[1 : 0]\} \sim \mathbb{F} \cup \{\alpha\}, \quad (2.2)$$

where  $\alpha$  denotes an element not in  $\mathbb{F}$  that can be seen as the point at infinity;

2. if  $d$  is a square in  $\mathbb{F}$  and  $s$  is a fixed square root of  $d$  in  $\mathbb{F}$ , then there is the factorization  $t^2 - d = (t + s)(t - s) \in \mathbb{F}[t]$  and, for any  $y \in \mathbb{F}$ , the classes  $[y(s + t)]$  and  $[y(-s + t)]$  are zero-divisors in  $\mathcal{R}_d$ , so that

$$\mathcal{R}_d^{\otimes_d} = \mathcal{R}_d \setminus \{[0], [sy + yt], [-sy + yt] \mid y \in \mathbb{F}\}.$$

Thus,

$$\mathbb{P}_d = \{[m : 1] \mid m \in \mathbb{F} \setminus \{\pm s\}\} \cup \{[1 : 0]\} \sim (\mathbb{F} \setminus \{\pm s\}) \cup \{\alpha\}. \quad (2.3)$$

The projectivization is actually a parameterization of the Pell conic, which is useful for studying some of its properties over finite fields and will be naturally generalized also for the cubic case. The following theorem provides an explicit group isomorphism between  $(\mathbb{P}_d, \otimes_d)$  and  $(\mathcal{C}_d, \otimes_d)$ . The result was introduced in [3], here we give a different formulation and a proof that can be adapted to the cubic case.

**Theorem 2.1.** Given  $d \in \mathbb{F}$ , the following map is a group isomorphism

$$\begin{aligned} \phi : (\mathbb{P}_d, \otimes_d) &\xrightarrow{\sim} (\mathcal{C}_d, \otimes_d), \\ [m : n] &\longmapsto \frac{(m, n)^{\otimes_{a^2}}}{N_d(m, n)} = \left( \frac{m^2 + dn^2}{m^2 - dn^2}, \frac{2mn}{m^2 - dn^2} \right), \end{aligned}$$

and its inverse is

$$\begin{aligned} \phi^{-1} : (\mathcal{C}_d, \otimes_d) &\xrightarrow{\sim} (\mathbb{P}_d, \otimes_d), \\ (-1, 0) &\longmapsto [0 : 1], \\ (x, y) &\longmapsto [x + 1 : y]. \end{aligned}$$

*Proof.* In order for  $\phi$  to be a group isomorphism, it must be:

- well defined: if  $[m : n] = [m' : n'] \in \mathbb{P}_d$ , then there is  $\lambda \in \mathbb{F}^\times$  such that  $[m' : n'] = [\lambda m : \lambda n]$ , and

$$\frac{(\lambda m, \lambda n)^{\otimes_{a^2}}}{N_d(\lambda m, \lambda n)} = \frac{\lambda^2(m, n)^{\otimes_{a^2}}}{\lambda^2 N_d(m, n)} = \frac{(m, n)^{\otimes_{a^2}}}{N_d(m, n)},$$

therefore  $\phi$  is well defined. In addition,  $\phi(\mathbb{P}_d) \subseteq \mathcal{C}_d$  since

$$N_d(\phi([m : n])) = \frac{N_d(m, n)^2}{N_d(m, n)^2} = 1;$$

- a group homomorphism: for any  $[m_1 : n_1], [m_2 : n_2] \in \mathbb{P}_d$  we have

$$[m_1 : n_1] \otimes_d [m_2 : n_2] = [m_1 m_2 + dn_1 n_2 : m_1 n_2 + n_1 m_2],$$

so that

$$\begin{aligned} \phi([m_1 : n_1] \otimes_d [m_2 : n_2]) &= \frac{(m_1 m_2 + dn_1 n_2, m_1 n_2 + n_1 m_2)^{\otimes_{a^2}}}{N_d(m_1 m_2 + dn_1 n_2, m_1 n_2 + n_1 m_2)} \\ &= \frac{(m_1, n_1)^{\otimes_{a^2}} \otimes_d (m_2, n_2)^{\otimes_{a^2}}}{N_d(m_1, n_1) N_d(m_2, n_2)} \\ &= \phi([m_1 : n_1]) \otimes_d \phi([m_2 : n_2]); \end{aligned}$$

- injective: for any  $[m : n] \in \mathbb{P}_d$ ,

$$\begin{aligned} \phi([m : n]) = (1, 0) &\Leftrightarrow \begin{cases} m^2 - dn^2 = m^2 + dn^2, \\ 0 = 2mn \end{cases} \\ &\Leftrightarrow n = 0 \Leftrightarrow \ker(\phi) = \{[1 : 0]\}; \end{aligned}$$

- surjective: if  $(x, 0) \in \mathcal{C}_d$ , then  $x^2 = 1$ , that is  $x = \pm 1$  and we have  $\phi([1 : 0]) = (1, 0)$  and  $\phi([0 : 1]) = (-1, 0)$ . Now let  $(x, y) \in \mathcal{C}_d$  with  $y \neq 0$ . We have  $d = \frac{x^2-1}{y^2}$  and, since  $d \neq 0$ ,  $x \neq \pm 1$ . In particular, we are looking for  $[m : n] \in \mathbb{P}_d$  such that

$$\begin{cases} x = \frac{m^2 y^2 + (x^2 - 1)n^2}{m^2 y^2 - (x^2 - 1)n^2}, \\ y = \frac{2mny^2}{m^2 y^2 - (x^2 - 1)n^2} \end{cases} \Leftrightarrow \begin{cases} m^2 y^2 - 2mny + n^2(x^2 - 1) = 0, \\ m^2 y^2 - 2mny - n^2(x^2 - 1) = 0. \end{cases}$$

Subtracting the second equation to the first one, we obtain

$$2n^2(x^2 - 1) = 2mn(x - 1).$$

Since  $x \neq 1$  and  $n \neq 0$ , we get  $m = n \frac{x+1}{y}$ . Therefore  $\phi([x+1 : y]) = (x, y)$  and this concludes the proof of the surjectivity.

In conclusion,  $\phi$  is a group isomorphism with the wanted inverse.  $\square$

When  $\phi^{-1}(x, y) = [x+1 : y] = [\frac{x+1}{y} : 1] = [m : 1]$ ,  $m$  can be interpreted geometrically: since  $x = my - 1$ , it represents the slope of the line through  $(x, y)$  and  $(-1, 0)$  written with  $x$  depending on  $y$ . With this interpretation,  $[1 : 0]$  is correctly seen as the slope of the horizontal line through  $(1, 0)$ , so that its relation with the point at infinity  $\alpha$  is coherent.

The group isomorphism  $\phi$  gives also a direct method to generate all the solutions of the Pell equation  $x^2 - dy^2 = 1 \in \mathbb{F}$  from the elements of  $\mathbb{P}_d$ , which require half the size to be stored when the notation introduced in Eqs. (2.2) and (2.3) is exploited, since

$$\begin{aligned} \phi(\alpha) &= \phi([1 : 0]) = (1, 0), \\ \phi(0) &= \phi([0 : 1]) = (-1, 0), \\ \phi(m) &= \phi([m : 1]) = \left( \frac{m^2 + d}{m^2 - d}, \frac{2m}{m^2 - d} \right), \quad \text{for } m \neq \alpha, 0. \end{aligned}$$

### 3 The Pell conic over finite fields

When  $\mathbb{F} = \mathbb{F}_q$ , with  $q = p^k$  and  $p$  prime, the group structure of the Pell conic depends on the parameter  $d$  being or not a square. These situations are fully described by Menezes and Vanstone [18] giving also the order of the Pell conic in these two cases, i.e., the number of solutions of the Pell equation over finite fields. In Sections 3.1 and 3.2, we report these results including the proofs and proving them also in an alternative way connected to the previous parameterization. In this way, we provide the ideas that will be exploited for studying the cubic Pell equation over finite fields in Section 5.

#### 3.1 $d$ non-square

When  $d$  is not a square,  $t^2 - d \in \mathbb{F}_q[t]$  is irreducible over  $\mathbb{F}_q$ , so that

$$\mathcal{R}_d = \mathbb{F}_q[t]/\langle t^2 - d \rangle \cong \mathbb{F}_{q^2}.$$

**Theorem 3.1.** If  $d$  is a non-square in  $\mathbb{F}_q$ , then  $(\mathcal{C}_d, \otimes_d)$  is a cyclic group of order  $q + 1$  [18].

*Proof.* We have that  $\mathcal{R}_d^{\otimes a} \cong \mathbb{F}_{q^2}^\times$  has  $q^2 - 1$  elements. If  $G \subset \mathbb{F}_{q^2}^\times$  denotes the multiplicative subgroup of order  $q + 1$ , then  $x + yt \in G \Leftrightarrow (x + yt)^{q+1} = 1$  and

$$\begin{aligned} (x + yt)^{q+1} &= (x + yt)^q(x + yt) \\ &= (x + yt^q)(x + yt) \\ &= (x + y(t^2)^{(q-1)/2}t)(x + yt) \\ &= (x + yd^{(q-1)/2}t)(x + yt) \\ &= (x - yt)(x + yt) \\ &= x^2 - dy^2, \end{aligned}$$

so that  $x + yt \in G \Leftrightarrow (x, y) \in \mathcal{C}_d$ . This association is a group isomorphism between  $G$  and  $(\mathcal{C}_d, \otimes_d)$ , hence the Pell conic is a cyclic group of order  $q + 1$ .  $\square$

Looking at the projectivization  $\mathbb{P}_d$ , since there are no square roots of  $d$  in  $\mathbb{F}_q$ , then  $\#\mathbb{P}_d = q + 1$  from Eq. (2.2). This is confirmed also considering

$$(\mathbb{P}_d, \otimes_d) = \mathcal{R}_d^{\otimes a} / \mathbb{F}_q^\times \cong \mathbb{F}_{q^2}^\times / \mathbb{F}_q^\times,$$

which proves also that  $(\mathbb{P}_d, \otimes_d)$  is cyclic because quotient of cyclic groups. Thus, using the group isomorphism  $\phi$  obtained for a general field in Theorem 2.1 also proves that  $(\mathcal{C}_d, \otimes_d)$  is cyclic of order  $q + 1$ . In addition,  $\phi$  allows also to describe each point of the conic with half the size with respect to the group isomorphism obtained in Theorem 3.1.

### 3.2 $d$ square

If we suppose  $d$  is a square and fix a square root  $s$  of  $d$ , then  $\pm s \in \mathbb{F}_q$  and  $\mathcal{R}_d$  is a ring. As in the previous case, the Pell conic is cyclic because of the following result.

**Theorem 3.2.** If  $d$  is a square in  $\mathbb{F}_q$ , then there is the group isomorphism

$$\begin{aligned} (\mathcal{C}_d, \otimes_d) &\cong \mathbb{F}_q^\times \\ (x, y) &\mapsto x - sy, \\ \left( \frac{1 + u^2}{2u}, \frac{1 - u^2}{2su} \right) &\longleftarrow u. \end{aligned}$$

Therefore  $(\mathcal{C}_d, \otimes_d)$  is a cyclic group of order  $q - 1$  [18].

*Proof.* Fix a square root  $s \in \mathbb{F}_q$  of  $d$ , the norm of a point  $(x, y) \in \mathcal{C}_d$  can be factorized as

$$1 = x^2 - dy^2 = (x - sy)(x + sy) = uv,$$

so that

$$x = \frac{v + u}{2}, \quad y = \frac{v - u}{2s},$$

which results in a bijective correspondence between  $(x, y) \in \mathcal{C}_d$  and  $(u, v) \in \mathbb{F}_q^2$  such that  $uv = 1$ . The equation  $uv = 1$  has exactly  $q - 1$  solutions  $\mathbb{F}_q^2$  and, in particular, a unique solution for each  $u \in \mathbb{F}_q^\times$ . Thus, the map in the statement is bijective and a group homomorphism, and  $(\mathcal{C}_d, \otimes_d)$  is cyclic of order  $q - 1$ .  $\square$

When considering the projectivization  $\mathbb{P}_d$ , Eq. (2.3) implies  $\#\mathbb{P}_d = q - 1$  and, as a corollary of Theorems 2.1 and 3.1, we have that  $\mathbb{P}_d$  is cyclic. However, as will be observed in Sections 4 and 5, we have a cubic analogous of Theorem 3.1 but not of Theorem 2.1. Thus, in order to have a starting point for the generalization in the cubic case with cube parameter (Sections 5.2 and 5.3), we give an alternative standalone proof of the structure of  $\mathbb{P}_d$  in the quadratic case.

**Theorem 3.3.** If  $d$  is a square in  $\mathbb{F}_q$ , then there is the group isomorphism

$$\begin{aligned} (\mathbb{P}_d, \otimes_d) &\cong \mathbb{F}_q^\times, \\ [m : n] &\mapsto \frac{m - sn}{m + sn}, \\ [s(1 + u) : 1 - u] &\longleftarrow u. \end{aligned}$$

Therefore,  $(\mathbb{P}_d, \otimes_d)$  is a cyclic group of order  $q - 1$ .

*Proof.* Fix  $s$  square root of  $d$  in  $\mathbb{F}_q$ ,  $t^2 - d$  is reducible over  $\mathbb{F}_q$  as

$$t^2 - d = (t - s)(t + s),$$

so that, using the Chinese remainder theorem, there is the ring isomorphism

$$\begin{aligned} \mathcal{R}_d = \mathbb{F}_q[t]/\langle t^2 - d \rangle &\xrightarrow{\sim} \mathbb{F}_q[t]/\langle t - s \rangle \times \mathbb{F}_q[t]/\langle t + s \rangle, \\ [x + yt] &\mapsto ([x + sy], [x - sy]). \end{aligned}$$

In addition,  $\mathbb{F}_q[t]/\langle t - s \rangle \cong \mathbb{F}_q[t]/\langle t + s \rangle \cong \mathbb{F}_q$ . When passing to the quotients, we obtain that

$$(\mathbb{P}_d, \otimes_d) = \mathcal{R}_d^{\otimes_d} / \mathbb{F}_q^\times \cong (\mathbb{F}_q^\times \times \mathbb{F}_q^\times) / \mathbb{F}_q^\times \cong \mathbb{F}_q^\times,$$

through the map in the statement. This confirms that  $(\mathbb{P}_d, \otimes_d)$  is a cyclic group of order  $q - 1$ .  $\square$

An interesting property of the explicit group isomorphisms obtained in Theorems 3.2 and 3.3 is that their composition gives the same group isomorphism obtained for a general field in Theorem 2.1. Indeed, the resulting map is

$$\begin{aligned} (\mathbb{P}_d, \otimes_d) &\xrightarrow{\sim} \mathbb{F}_q^\times \xrightarrow{\sim} (\mathcal{C}_d, \otimes_d), \\ [m : n] &\mapsto \frac{m - sn}{m + sn} \mapsto \left( \frac{1 + \left(\frac{m - sn}{m + sn}\right)^2}{2\frac{m - sn}{m + sn}}, \frac{1 - \left(\frac{m - sn}{m + sn}\right)^2}{2s\frac{m - sn}{m + sn}} \right) = (x, y). \end{aligned}$$

We have

$$\begin{aligned} (x, y) &= \left( \frac{(m + sn)^2 + (m - sn)^2}{2(m - sn)(m + sn)}, \frac{(m + sn)^2 - (m - sn)^2}{2s(m - sn)(m + sn)} \right) \\ &= \left( \frac{2m^2 + 2dn^2}{2(m^2 - dn^2)}, \frac{4smn}{2s(m^2 - dn^2)} \right) = \left( \frac{m^2 + dn^2}{m^2 - dn^2}, \frac{2mn}{m^2 - dn^2} \right), \end{aligned}$$

which is exactly the isomorphism  $\phi$  obtained for a general field in Theorem 2.1.

On the other hand, the inverse is given by

$$\begin{aligned} (\mathcal{C}_d, \otimes_d) &\xrightarrow{\sim} \mathbb{F}_q^\times && \xrightarrow{\sim} (\mathbb{P}_d, \otimes_d), \\ (x, y) &\longmapsto x - sy && \longmapsto [s(1+x-sy) : 1-x+sy] = [m : n]. \end{aligned}$$

If  $1+x+sy \neq 0$ , then we have

$$\begin{aligned} [m : n] &= [s(1+x-sy)(1+x+sy) : (1-x+sy)(1+x+sy)] \\ &= [s(1+2x+x^2-dy^2) : 1+2sy+dy^2-x^2] \\ &= [2s(1+x) : 2sy] = [1+x : y]. \end{aligned}$$

On the other hand, if  $1+x+sy = 0$ , then we have

$$\begin{cases} 1+x+sy = 0, \\ x^2-dy^2 = 1 \end{cases} \Rightarrow \begin{cases} x = -1-sy, \\ 1+2sy+dy^2-dy^2 = 1 \end{cases} \Rightarrow \begin{cases} x = -1, \\ y = 0, \end{cases}$$

so that

$$[m : n] = \begin{cases} [0 : 1], & \text{if } (x, y) = (-1, 0), \\ [1+x : y], & \text{otherwise.} \end{cases}$$

This is exactly the isomorphism  $\phi^{-1}$  obtained for a general field in Theorem 2.1.

## 4 The cubic Pell equation

In this section, we introduce and study the cubic Pell equation in a way similar to the one used in Section 2 for the quadratic case. Then we approach the study of the Pell cubic equation over finite fields in the next section.

Given a field  $\mathbb{F}$  and an element  $r \in \mathbb{F}$ , we consider the polynomial ring

$$\begin{aligned} \mathcal{R}_r &:= \mathbb{F}[t]/\langle t^3 - r \rangle \\ &= \{[x + yt + zt^2] = [x + yt + zt^2 + k(t)(t^3 - r) \mid k(t) \in \mathbb{F}[t] \mid x, y, z \in \mathbb{F}\}, \end{aligned}$$

which inherits from the polynomial product the operation

$$\begin{aligned} [x_1 + y_1t + z_1t^2] \cdot [x_2 + y_2t + z_2t^2] &= [x_1x_2 + r(y_1z_2 + z_1y_2) \\ &\quad + (x_1y_2 + y_1x_2 + rz_1z_2)t \\ &\quad + (x_1z_2 + y_1y_2 + z_1x_2)t^2]. \end{aligned}$$

Considering the cubic roots of unity  $\{1, \omega, \omega^2\}$ , an element  $[x + yt + zt^2] \in \mathcal{R}_r$  has two conjugates

$$[x + y\omega t + z\omega^2t^2], \quad [x + y\omega^2t + z\omega t^2],$$

which we use analogously to the quadratic case to define the norm

$$\begin{aligned} N_r[x + yt + zt^2] &:= [x + yt + zt^2] \cdot [x + y\omega t + z\omega^2t^2] \cdot [x + y\omega^2t + z\omega t^2] \\ &= x^3 - 3rxyz + ry^3 + r^2z^3. \end{aligned}$$

As for the Pell conic, this allows to provide a trivial group isomorphism between the unitary elements of  $\mathcal{R}_r$  with respect to the norm  $N_r$

$$\mathcal{U}(\mathcal{R}_r) := \{[x + yt + zt^2] \in \mathcal{R}_r \mid N_r[x + yt + zt^2] = 1\},$$

and the *Pell cubic*

$$\mathcal{C}_r := \{(x, y, z) \in \mathbb{F}^3 \mid x^3 - 3rxyz + ry^3 + r^2z^3 = 1\},$$

that, with the generalization of the Brahmagupta product

$$\begin{aligned} (x_1, y_1, z_1) \odot_r (x_2, y_2, z_2) := & (x_1x_2 + r(y_1z_2 + z_1y_2), \\ & x_1y_2 + y_1x_2 + rz_1z_2, \\ & x_1z_2 + y_1y_2 + z_1x_2), \end{aligned}$$

is a commutative group with identity  $(1, 0, 0)$  and inverse of an element  $(x, y, z)$  given by the product of its conjugates

$$(x, y\omega, z\omega^2) \odot_r (x, y\omega^2, z\omega) = (x^2 - ryz, rz^2 - xy, y^2 - xz).$$

Due to this group isomorphism, in the following we will use the norm  $N_r$  also for the points of the cubic and the notation  $\odot_r$  also for denoting the product over  $\mathcal{R}_r$ . In general, we denote by  $(x, y, z)^{\odot_r k}$  the  $k$ -power of  $(x, y, z)$  with  $\odot_r$ .

As for Definition 2.1, we can consider the set of the invertible elements of  $\mathcal{R}_r$  with respect to  $\odot_r$ , denoted as

$$\mathcal{R}_r^{\odot_r} := \{[x + yt + zt^2] \in \mathcal{R}_r \mid N_r[x + yt + zt^2] \neq 0\},$$

as well as introduce a projectivization related to the Pell cubic.

**Definition 4.1.** The projectivization of  $\mathcal{R}_r$  is  $\mathbb{P}_r := \mathcal{R}_r^{\odot_r} / \mathbb{F}^\times$ , so that the elements of  $\mathbb{P}_r$  are the classes of equivalence of the elements  $[l + mt + nt^2] \in \mathcal{R}_r^{\odot_r}$ , i.e., they are of the form

$$[l : m : n] := \{\lambda[l + mt + nt^2] \mid \lambda \in \mathbb{F}^\times\}.$$

If  $n \in \mathbb{F}^\times$ , then  $[l + mt + nt^2]$  is equivalent to  $[ln^{-1} + mn^{-1}t + t^2]$  and we choose  $[ln^{-1} : mn^{-1} : 1]$  as canonical representative in  $\mathbb{P}_r$ . Otherwise, if  $n = 0$  and  $m \in \mathbb{F}^\times$ , then we can take  $[lm^{-1} : 1 : 0]$  and finally, when  $m = n = 0$ , the canonical representative is  $[1 : 0 : 0]$ .

Since the product  $\odot_r$  consists of homogeneous polynomials, it is well defined also on  $\mathbb{P}_r$  and determines a commutative group with identity  $[1 : 0 : 0]$  and inverse of  $[l : m : n]$  given by  $[l^2 - rmn : rn^2 - lm : m^2 - ln]$ , i.e.,

$$\begin{aligned} [l : m : 1] \odot_r [l^2 - rm : r - lm : m^2 - l] &= [1 : 0 : 0], \\ [l : 1 : 0] \odot_r [l^2 : -l : 1] &= [1 : 0 : 0]. \end{aligned}$$

Differently from the quadratic case, the group isomorphism between  $(\mathbb{P}_r, \odot_r)$  and  $(\mathcal{C}_r, \odot_r)$  is not easy to find. However, we study the structure of the projectivization depending on the parameter  $r$  since it is useful for giving a complete characterization of the Pell cubic over finite fields, i.e., generalizing the results in Section 3. Specifically, there are three possible cases:

1. if  $r$  is not a cube in  $\mathbb{F}$ , then  $N_r[x + yt + zt^2] \neq 0 \Leftrightarrow [x + yt + zt^2] \neq [0]$  and

$$\begin{aligned} \mathbb{P}_r &= \{[l : m : 1], [l : 1 : 0], [1 : 0 : 0] \mid l, m \in \mathbb{F}\} \\ &\sim (\mathbb{F} \times \mathbb{F}) \cup (\mathbb{F} \times \{\alpha\}) \cup \{(\alpha, \alpha)\}, \end{aligned} \quad (4.1)$$

where  $(\alpha, \alpha)$  denotes the point at infinity and  $\mathbb{F} \times \{\alpha\}$  is a line at infinity;

2. if  $r$  is a cube and  $\{1, \omega, \omega^2\} \subset \mathbb{F}$ , then  $\mathbb{F}$  contains also all the cubic roots of  $r$  that, when denoting one of them with  $s$ , are  $\{s, s\omega, s\omega^2\}$ . In this case,  $t^3 - r = (t - s)(t - s\omega)(t - s\omega^2)$  and the elements of norm zero in  $\mathcal{R}_r$  must be multiples of the classes of the three zero-divisors, i.e.,

$$\{[x + yt + zt^2] \in \mathcal{R}_r \mid N_r[x + yt + zt^2] = 0\} = \langle [t - s], [t - s\omega], [t - s\omega^2] \rangle.$$

Looking at the projectivization, this means that

$$\mathbb{P}_r = \{[l : m : n] \mid l, m, n \in \mathbb{F}\} \setminus \langle [-s : 1 : 0], [-s\omega : 1 : 0], [-s\omega^2 : 1 : 0] \rangle.$$

Hence, in order to obtain an explicit form for  $\mathbb{P}_r$  like in Eq. (4.1), we need to study the multiples of these three elements.

The multiples of  $[-s : 1 : 0]$  are, for any  $l \in \mathbb{F}$ ,

$$[-s : 1 : 0] \odot_r [l : 1 : 0] = [-ls : -s + l : 1],$$

and, for any  $l', m' \in \mathbb{F}$ ,

$$\begin{aligned} [-s : 1 : 0] \odot_r [l' : m' : 1] &= [-l's + s^3 : -m's + l' : -s + m'] \\ &= \begin{cases} [-s(l' - s^2) : l' - s^2 : 0], & \text{if } m' = s, \\ \left[ -\left(\frac{l' - s^2}{m' - s}\right) s : \left(\frac{l' - s^2}{m' - s}\right) - s : 1 \right], & \text{otherwise} \end{cases} \\ &= \begin{cases} [-s : 1 : 0], & \text{if } m' = s, \\ [-ls : l - s : 1], & \text{with } l = \frac{l' - s^2}{m' - s} \text{ otherwise.} \end{cases} \end{aligned}$$

We obtain analogous results for the other multiples, specifically

$$\begin{aligned} \langle [-s : 1 : 0] \rangle &= \{[-s : 1 : 0], [-ls : l - s : 1] \mid l \in \mathbb{F}\}, \\ \langle [-s\omega : 1 : 0] \rangle &= \{[-s\omega : 1 : 0], [-ls\omega : l - s\omega : 1] \mid l \in \mathbb{F}\}, \\ \langle [-s\omega^2 : 1 : 0] \rangle &= \{[-s\omega^2 : 1 : 0], [-ls\omega^2 : l - s\omega^2 : 1] \mid l \in \mathbb{F}\}. \end{aligned} \quad (4.2)$$

In order to list precisely the elements of  $\mathbb{P}_r$ , we still need to study the intersections between the three obtained sets: if  $0 \leq i < j \leq 2$ , then  $[-ls\omega^i : l - s\omega^i : 1] = [-l's\omega^j : l' - s\omega^j : 1]$  if and only if

$$\begin{cases} -ls\omega^i = -l's\omega^j, \\ l - s\omega^i = l' - s\omega^j \end{cases} \Leftrightarrow \begin{cases} l = l'\omega^{j-i}, \\ l'\omega^{j-i} - l' = s\omega^i - s\omega^j \end{cases} \Leftrightarrow \begin{cases} l = -s\omega^j, \\ l' = -s\omega^i. \end{cases}$$

This means that, for any  $0 \leq i < j \leq 2$ ,

$$\begin{aligned} \langle (-s\omega^i, 1, 0) \rangle \cap \langle (-s\omega^j, 1, 0) \rangle &= \{[s^2\omega^{i+j} : -s(\omega^i + \omega^j) : 1]\} \\ &= \{[s^2\omega^{i+j} : s\omega^k : 1], k = 3 - i - j\}. \end{aligned}$$

Thus, when listing the elements of  $\mathbb{P}_r$  by using the sets in Eq. (4.2), we have to consider that three elements are obtained twice. In particular, in  $\langle [-s\omega^i : 1 : 0] \rangle$ , they are those with second coordinate  $m = s\omega^k$  for  $k \neq i$ . For instance, one of the duplicates can be removed by the list by excluding for each  $i \in \{0, 1, 2\}$  the element with  $m = s\omega^{i-1}$ , so that

$$\begin{aligned} \mathbb{P}_r = & \{ [l : m : 1], [l : 1 : 0], [1 : 0 : 0] \mid l, m \in \mathbb{F} \} \\ & \setminus \bigcup_{i \in \{0, 1, 2\}} \{ [-s\omega^i : 1 : 0], [-(m+s\omega^i)s\omega^i : m : 1] \mid m \in \mathbb{F} \setminus \{s\omega^{i-1}\} \}. \end{aligned} \quad (4.3)$$

3. if  $r$  is a cube and  $\mathbb{F}$  does not contain any non-trivial cubic root of unity, i.e.,  $\{\omega, \omega^2\} \not\subset \mathbb{F}$ , then only one root  $s$  of  $r$  is in  $\mathbb{F}$  and in  $\mathbb{F}[t]$

$$t^3 - r = (t - s)(t^2 + st + s^2).$$

The elements of norm zero are multiple of the zero-divisors, i.e.,

$$\{ [x + yt + zt^2] \in \mathcal{R}_r \mid N_r[x + yt + zt^2] = 0 \} = \langle [t - s], [t^2 + st + s^2] \rangle.$$

As before, when considering the projectivization, the non-trivial multiples of  $[-s : 1 : 0]$  are  $[-(m+s)s : m : 1]$  for  $m \in \mathbb{F}$ .

This list already contains all the non-trivial multiples of the second zero-divisor since for every  $[l : m : n]$  non multiple of  $[-s : 1 : 0]$ , we have

$$\begin{aligned} [s^2 : s : 1] \odot_r [l : m : n] &= [s^2(l+ms+ns^2) : s(l+ms+ns^2) : l+ms+ns^2] \\ &= [s^2 : s : 1]. \end{aligned}$$

In conclusion, the elements in the projectivization are exactly

$$\begin{aligned} \mathbb{P}_r = & \{ [l : m : 1], [l : 1 : 0], [1 : 0 : 0] \mid l, m \in \mathbb{F} \} \\ & \setminus \{ [-s : 1 : 0], [-(m+s)s : m : 1], [s^2 : s : 1] \mid m \in \mathbb{F} \}. \end{aligned} \quad (4.4)$$

## 5 The Pell cubic over finite fields

In this section, we give a full description of the solutions of the cubic Pell equation when  $\mathbb{F} = \mathbb{F}_q$  with  $q = p^k$  and  $p$  prime. This characterization depends on the parameter  $r \in \mathbb{F}_q$  and there are three different scenarios due to the value of  $\gcd(3, q-1)$  in the extended Euler criterion:

$$r \in \mathbb{F}_q \text{ is a cube} \Leftrightarrow r^{(q-1)/\gcd(3, q-1)} = 1.$$

### 5.1 $r$ non-cube

From the Euler criterion, a finite field  $\mathbb{F}_q$  contains a non-cube element  $r$  if and only if  $\gcd(3, q-1) > 1 \Leftrightarrow q \equiv 1 \pmod{3}$ , so that  $(q-1)/3 = \lfloor q/3 \rfloor$  and

$$\begin{cases} r^{(q-1)/3} \neq 1, \\ r^{q-1} = 1 \end{cases} \Leftrightarrow r^{\lfloor q/3 \rfloor} = \omega, \text{ primitive cubic root of unity.}$$

In this case, the polynomial  $t^3 - r$  is irreducible over  $\mathbb{F}_q$ , so that

$$\mathcal{R}_r = \mathbb{F}_q[t]/\langle t^3 - r \rangle \cong \mathbb{F}_{q^3}.$$

We can obtain a result analogous to Theorem 3.1.

**Theorem 5.1.** If  $r$  is a non-cube in  $\mathbb{F}_q$ , then  $(\mathcal{C}_r, \odot_r)$  is a cyclic group of order  $q^2 + q + 1$ .

*Proof.* We clearly have that  $\mathcal{R}_r^{\odot_r} \cong \mathbb{F}_{q^3}^\times$  has  $q^3 - 1$  elements. If  $G \subset \mathbb{F}_{q^3}^\times$  denotes the multiplicative subgroup of order  $q^2 + q + 1$ , then  $x + yt + zt^2 \in G$  if and only if  $(x + yt + zt^2)^{q^2+q+1} = 1$  and

$$\begin{aligned} (x + yt + zt^2)^{q^2+q+1} &= (x + yt + zt^2)^{q^2} (x + yt + zt^2)^q (x + yt + zt^2) \\ &= (x + yt^q + zt^{2q})^q (x + yt^q + zt^{2q}) (x + yt + zt^2), \end{aligned}$$

where

$$t^q = (t^3)^{(q-1)/3} t = r^{\lfloor q/3 \rfloor} t = \omega t, \quad \omega^q = (\omega^3)^{(q-1)/3} \omega = \omega,$$

so that

$$\begin{aligned} (x + yt + zt^2)^{q^2+q+1} &= (x + y\omega t + z\omega^2 t^2)^q (x + y\omega t + z\omega^2 t^2) (x + yt + zt^2) \\ &= (x + y\omega^q t^q + z\omega^{2q} t^{2q}) (x + y\omega t + z\omega^2 t^2) (x + yt + zt^2) \\ &= (x + y\omega^2 t + z\omega t^q) (x + y\omega t + z\omega^2 t^2) (x + yt + zt^2) \\ &= x^3 - 3rxyz + ry^3 + r^2z^3. \end{aligned}$$

Thus,  $x + yt + zt^2 \in G \Leftrightarrow (x, y, z) \in \mathcal{C}_r$ . This association is a group isomorphism between  $G$  and  $(\mathcal{C}_r, \odot_r)$ , hence the Pell cubic is cyclic with order  $q^2 + q + 1$ .  $\square$

Looking at the projectivization  $\mathbb{P}_r$ , since there are no cubic roots of  $r$  in  $\mathbb{F}_q$ , then  $\#\mathbb{P}_r = q^2 + q + 1$  from Eq. (4.1). This is obtained also considering that

$$(\mathbb{P}_r, \odot_r) = \mathcal{R}_r^{\odot_r} / \mathbb{F}_q^\times \cong \mathbb{F}_{q^3}^\times / \mathbb{F}_q^\times,$$

which proves also that  $(\mathbb{P}_r, \odot_r)$  is cyclic because quotient of cyclic groups. In addition, it is possible to obtain the following result.

**Theorem 5.2.** If  $q \equiv 1 \pmod{3}$  and  $r \in \mathbb{F}_q^\times$  is a non-cube, then there is the group isomorphism

$$\begin{aligned} \psi_1 : (\mathbb{P}_r, \odot_r) &\xrightarrow{\sim} (\mathcal{C}_r, \odot_r), \\ [l : m : n] &\mapsto N_r(l, m, n)^{\lfloor q/3 \rfloor - 1} (l, m, n)^{\odot_r 3}. \end{aligned}$$

*Proof.* In order for  $\psi_1$  to be a group isomorphism, it must be:

- well defined: if  $[l : m : n] = [l' : m' : n'] \in \mathbb{P}_r$ , then there is  $\lambda \in \mathbb{F}^\times$  such that  $[l' : m' : n'] = [\lambda l : \lambda m : \lambda n]$ , and since  $\lfloor q/3 \rfloor - 1 = (q - 4)/3$

$$\begin{aligned} N_r(\lambda l, \lambda m, \lambda n)^{\frac{q-4}{3}} (\lambda l, \lambda m, \lambda n)^{\odot_r 3} &= (\lambda^3 N_r(l, m, n))^{\frac{q-4}{3}} \lambda^3 (l, m, n)^{\odot_r 3} \\ &= \lambda^{q-1} N_r(l, m, n)^{\frac{q-4}{3}} (l, m, n)^{\odot_r 3}, \end{aligned}$$

therefore  $\psi_1$  is well defined. In addition,  $\psi_1(\mathbb{P}_r) \subseteq \mathcal{C}_r$  because

$$\begin{aligned} N_r(\psi_1([l : m : n])) &= N_r(l, m, n)^{q-4} N_r(l, m, n)^3 \\ &= N_r(l, m, n)^{q-1} = 1; \end{aligned}$$

- a group homomorphism: given  $[l_1 : m_1 : n_1], [l_2 : m_2 : n_2] \in \mathbb{P}_r$ , by denoting  $[l : m : n] = [l_1 : m_1 : n_1] \odot_r [l_2 : m_2 : n_2]$ , we have

$$\begin{aligned}\psi_1([l : m : n]) &= N_r(l, m, n)^{\lfloor q/3 \rfloor - 1} (l, m, n)^{\odot_r 3} \\ &= N_r(l_1, m_1, n_1)^{\lfloor q/3 \rfloor - 1} N_r(l_2, m_2, n_2)^{\lfloor q/3 \rfloor - 1} \\ &\quad (l_1, m_1, n_1)^{\odot_r 3} \odot_r (l_2, m_2, n_2)^{\odot_r 3} \\ &= \psi_1([l_1 : m_1 : n_1]) \odot_r \psi_1([l_2 : m_2 : n_2]);\end{aligned}$$

- injective: for any  $[l : m : n] \in \mathbb{P}_r$ ,  $\psi_1([l : m : n]) = (1, 0, 0)$  if and only if

$$\begin{cases} N_r(l, m, n)^{\lfloor q/3 \rfloor - 1} (l^3 + 6rlmn + rm^3 + r^2n^3) = 1, \\ N_r(l, m, n)^{\lfloor q/3 \rfloor - 1} (l^2m + rln^2 + rm^2n) = 0, \\ N_r(l, m, n)^{\lfloor q/3 \rfloor - 1} (l^2n + lm^2 + rmn^2) = 0, \end{cases}$$

with  $N_r(l, m, n) \neq 0$ , so that:

- if  $m, n \neq 0$ , then

$$\begin{cases} l^2mn + rln^3 + rm^2n^2 = 0, \\ l^2mn + lm^3 + rm^2n^2 = 0 \end{cases} \Leftrightarrow l(rn^3 - m^3) = 0.$$

Since  $r$  is not a cube, the only solution is  $l = 0$ . However, this implies that  $rm^2n^2 = 0$ , which is satisfied only if  $m = 0$  or  $n = 0$ . Therefore, there are no solutions such that  $m, n \neq 0$ ;

- if  $m \neq n = 0$ , then from the third equation  $lm^2 = 0$ , i.e.,  $l = 0$ , so that  $[l : m : n] = [0 : 1 : 0]$  and the first equation becomes  $r^{\lfloor q/3 \rfloor} = 1$ . This is in contradiction with  $r^{(q-1)/3} = \omega$  deduced from our assumption at the beginning of the subsection. Therefore, there are no solutions such that  $m \neq n = 0$ ;
- if  $n \neq m = 0$ , then from the second equation  $rln^2 = 0$ , i.e.,  $l = 0$ , so that  $[l : m : n] = [0 : 0 : 1]$  and the first equation becomes  $r^{2\lfloor q/3 \rfloor} = 1$ , i.e.,  $r^{(q-1)/3} = \pm 1$ . The case  $r^{(q-1)/3} = 1$  is again in contradiction with  $r^{(q-1)/3} = \omega$  obtained from the extended Euler criterion. On the other hand,  $r^{(q-1)/3} = -1$  implies  $r^{q-1} = -1$ , which does not respect the field order. Therefore, there are no solutions such that  $n \neq m = 0$ ;
- $m = n = 0$  implies  $[l : m : n] = [1 : 0 : 0]$  which is a solution.

We have finally proved that  $\ker(\psi_1) = \{[1 : 0 : 0]\}$ ;

- the surjectivity follows from the fact that we have an injective map between two finite groups of same cardinality  $q^2 + q + 1$ .

In conclusion,  $\psi_1$  is a group isomorphism.  $\square$

Thus, using the group isomorphism  $\psi_1$  also proves that  $(\mathcal{C}_r, \odot_r)$  is cyclic of order  $q^2 + q + 1$ . This construction allows also to find all the solutions of the cubic Pell equation. Indeed, it is sufficient to evaluate  $\psi_1$  over all the elements of  $\mathbb{P}_r$ , which are  $[l : m : 1]$  for all  $l, m \in \mathbb{F}_q$ ,  $[l : 1 : 0]$  for all  $l \in \mathbb{F}_q$  and  $[1 : 0 : 0]$ , as obtained in Eq. (4.1). However, since the explicit inverse is missing, it is difficult to describe each point of the Pell cubic as a point of the projectivization.

**Example 5.1.** Let us consider  $q = 7$  and  $r = 2$ , which is not a cube in  $\mathbb{F}_7$ . Thanks to the previous results we know that the cubic Pell equation

$$x^3 + 2y^3 + 4z^3 - 6xyz \equiv 1 \pmod{7},$$

admits  $q^2 + q + 1 = 57$  solutions and we are able to find all of them evaluating

$$\begin{aligned} \psi_1([l : m : 1]), \quad \forall l, m \in \mathbb{F}_7, \\ \psi_1([l : 1 : 0]), \quad \forall l \in \mathbb{F}_7, \\ \psi_1([1 : 0 : 0]) = (1, 0, 0). \end{aligned}$$

For instance, for finding a random solution of the cubic Pell equation, we can take two random elements  $l, m \in \mathbb{F}_7$ , e.g.,  $l = 3$  and  $m = 5$  and evaluate

$$\psi_1([3 : 5 : 1]) = (5, 4, 4).$$

One can check that

$$5^3 + 2 \cdot 4^3 + 4 \cdot 4^3 - 6 \cdot 5 \cdot 4 \cdot 4 \equiv 1 \pmod{7}.$$

Similarly, we can take  $l = 4$  and  $[4 : 1 : 0] \in \mathbb{P}_2$ , so that

$$\psi_1([4 : 1 : 0]) = (2, 4, 1),$$

is another solution of the cubic Pell equation.

Note that for large values of  $q$  this method for finding all the solutions of the cubic Pell equation is not efficient, since it has complexity  $O(q^2)$ , even if it is surely better than an exhaustive search that has complexity  $O(q^3)$ .

However, for large values of  $q$  it is really interesting to use the above method for generating random solutions of the cubic Pell equation since, exploiting  $\psi_1$  as in the previous example, we are always able to generate different solutions.

## 5.2 $r$ cube with three roots in $\mathbb{F}_q$

If  $q \equiv 1 \pmod{3}$ , given  $\omega$  primitive cubic root of unity, then  $\{1, \omega, \omega^2\} \subset \mathbb{F}_q$ . In addition, if  $r$  is a cube and  $s \in \mathbb{F}_q^\times$  is a fixed cubic root of  $r$ , then the other two cubic roots are  $\omega s, \omega^2 s$  and  $\{s, \omega s, \omega^2 s\} \subseteq \mathbb{F}_q^\times$ . In this case, with a proof analogous to Theorem 3.2, we prove the following result.

**Theorem 5.3.** If  $q \equiv 1 \pmod{3}$  and  $r \in \mathbb{F}_q^\times$  is a cube, then  $(\mathcal{C}_r, \odot_r)$  is isomorphic to  $\mathbb{F}_q^\times \times \mathbb{F}_q^\times$  through

$$\begin{aligned} (\mathcal{C}_r, \odot_r) &\cong \mathbb{F}_q^\times \times \mathbb{F}_q^\times \\ (x, y, z) &\longmapsto (x + \omega sy + \omega^2 s^2 z, x + \omega^2 sy + \omega s^2 z), \\ \left( \frac{1 + uv^2 + u^2 v}{3uv}, \frac{1 + \omega uv^2 + \omega^2 u^2 v}{3suv}, \frac{1 + \omega^2 uv^2 + \omega u^2 v}{3s^2 uv} \right) &\longleftarrow (u, v). \end{aligned}$$

*Proof.* Fix a cubic root  $s \in \mathbb{F}_q^\times$  of  $r$ , the norm of a point  $(x, y, z) \in \mathcal{C}_r$  can be written as

$$\begin{aligned} 1 &= x^3 - 3rxyz + ry^3 + r^2 z^3 \\ &= (x + \omega sy + \omega^2 s^2 z)(x + \omega^2 sy + \omega s^2 z)(x + sy + s^2 z) = uvw, \end{aligned}$$

so that

$$x = \frac{w + v + u}{3}, \quad y = \frac{w + \omega v + \omega^2 u}{3s}, \quad z = \frac{w + \omega^2 v + \omega u}{3s^2},$$

is a bijective correspondence between the points  $(x, y, z) \in \mathcal{C}_r$  and  $(u, v, w) \in \mathbb{F}_q^3$  such that  $uvw = 1$ . The equation  $uvw = 1$  has exactly  $(q-1)^2$  solutions in  $\mathbb{F}_q^3$  and, in particular, a unique solution for each  $(u, v) \in \mathbb{F}_q^\times \times \mathbb{F}_q^\times$ . Thus, the map in the statement is bijective and also a group homomorphism.  $\square$

When considering the projectivization  $\mathbb{P}_r$ , it is clear from Eq. (4.3) that

$$\#\mathbb{P}_r = q^2 + q + 1 - 3q = (q-1)^2.$$

This is confirmed by the following result, obtained analogously to Theorem 3.3.

**Theorem 5.4.** If  $q \equiv 1 \pmod{3}$  and  $r \in \mathbb{F}_q^\times$  is a cube, then  $(\mathbb{P}_r, \odot_r)$  is isomorphic to  $\mathbb{F}_q^\times \times \mathbb{F}_q^\times$  through

$$\begin{aligned} (\mathbb{P}_r, \odot_r) &\cong \mathbb{F}_q^\times \times \mathbb{F}_q^\times, \\ [l : m : n] &\mapsto \left( \frac{l + \omega sm + \omega^2 s^2 n}{l + sm + s^2 n}, \frac{l + \omega^2 sm + \omega s^2 n}{l + sm + s^2 n} \right), \\ [s^2(1+v+u) : s(1+\omega v + \omega^2 u) : 1 + \omega^2 v + \omega u] &\leftrightarrow (u, v). \end{aligned}$$

*Proof.* Fix  $s$  cubic root of  $r$  in  $\mathbb{F}_q$ ,  $t^3 - r$  is reducible over  $\mathbb{F}_q$  as

$$t^3 - r = (t - s)(t - \omega s)(t - \omega^2 s),$$

so that, using the Chinese remainder theorem, there is the ring isomorphism

$$\begin{aligned} \mathcal{R}_r = \mathbb{F}_q[t]/\langle t^3 - r \rangle &\xrightarrow{\sim} \mathbb{F}_q[t]/\langle t - s \rangle \times \mathbb{F}_q[t]/\langle t - \omega s \rangle \times \mathbb{F}_q[t]/\langle t - \omega^2 s \rangle, \\ x + yt + zt^2 &\mapsto (x + sy + s^2 z, x + \omega sy + \omega^2 s^2 z, x + \omega^2 sy + \omega s^2 z). \end{aligned}$$

In addition,  $\mathbb{F}_q[t]/\langle t - s \rangle \cong \mathbb{F}_q[t]/\langle t - \omega s \rangle \cong \mathbb{F}_q[t]/\langle t - \omega^2 s \rangle \cong \mathbb{F}_q$ . When passing to the quotients, we obtain that

$$(\mathbb{P}_r, \odot_r) = \mathcal{R}_r^{\odot_r} / \mathbb{F}_q^\times \cong (\mathbb{F}_q^\times \times \mathbb{F}_q^\times \times \mathbb{F}_q^\times) / \mathbb{F}_q^\times \cong \mathbb{F}_q^\times \times \mathbb{F}_q^\times,$$

through the map in the statement.  $\square$

Combining the obtained results gives the explicit group isomorphism

$$\begin{aligned} \psi_2 : (\mathbb{P}_r, \odot_r) &\xrightarrow{\sim} (\mathcal{C}_r, \odot_r), \\ [l : m : n] &\mapsto \left( \frac{l^3 + 2s^2 l(m^2 + smn + s^2 n^2) + s^4 mn(m + sn)}{N_r(l, m, n)}, \right. \\ &\quad \frac{s^2 m^3 + 2m(l^2 + s^2 ln + s^4 n^2) + sln(l + s^2 n)}{N_r(l, m, n)}, \\ &\quad \left. \frac{s^5 n^3 + 2sn(l^2 + slm + s^2 m^2) + lm(l + sm)}{sN_r(l, m, n)} \right), \end{aligned}$$

where the sum of the numerators is  $(l + sm + s^2 n)^3$ . The inverse is given by

$$\begin{aligned} \psi_2^{-1} : (\mathcal{C}_r, \odot_r) &\xrightarrow{\sim} (\mathbb{P}_r, \odot_r), \\ (x, y, z) &\mapsto [s^2(1+2x-sy-s^2z) : s(1-x+2sy-s^2z) : 1-x-sy+2s^2z]. \end{aligned}$$

The group isomorphism  $\psi_2$  allows to find all the solutions of the cubic Pell equation: it is sufficient to evaluate  $\psi_2$  over all the elements of  $\mathbb{P}_r$  described explicitly in Eq. (4.3). In addition, differently from the previous case, the explicit inverse of the group isomorphism can be used to describe each point of the Pell cubic with two thirds of the size with respect to the classical notation for the points in  $\mathbb{F}_q^3$ .

**Example 5.2.** Let us consider  $q = 13$  and  $r = 5$ , which is the cube of  $\{7, 8, 11\}$  in  $\mathbb{F}_{13}$ . Thanks to the previous results we know that the cubic Pell equation

$$x^3 + 5y^3 - z^3 - 2xyz \equiv 1 \pmod{13},$$

admits  $(q - 1)^2 = 144$  solutions and we are able to find all of them evaluating

$$\begin{aligned} \psi_2([l : m : 1]), \quad \forall m \in \mathbb{F}_{13}, l \in \mathbb{F}_{13} \setminus \{-7m + 3, -8m + 1, -11m + 9\}, \\ \psi_2([l : 1 : 0]), \quad \forall l \in \mathbb{F}_{13} \setminus \{-7, -8, -11\}, \\ \psi_2([1 : 0 : 0]) = (1, 0, 0). \end{aligned}$$

For instance, for finding a random solution of the cubic Pell equation, we can take a random  $m \in \mathbb{F}_{13}$ , e.g.,  $m = 3$ , and another element  $l \in \mathbb{F}_{13} \setminus \{8, 3, 2\}$ , e.g.,  $l = 9$ , and evaluate

$$\psi_2([9 : 3 : 1]) = (3, 4, 3).$$

One can check that

$$3^3 + 5 \cdot 4^3 - 3^3 - 2 \cdot 3 \cdot 4 \cdot 3 \equiv 1 \pmod{13}.$$

Similarly, we can take  $l = 4 \notin \{6, 5, 2\}$  and  $[4 : 1 : 0] \in \mathbb{P}_5$ , so that

$$\psi_1([4 : 1 : 0]) = (10, 4, 9),$$

is another solution of the cubic Pell equation.

### 5.3 $r$ cube with one root in $\mathbb{F}_q$

If  $q \not\equiv 1 \pmod{3}$ , then  $\mathbb{F}_q$  does not contain any non-trivial cubic root of unity. In addition, each  $r \in \mathbb{F}_q^\times$  is a cube and has only one cubic root  $s$  in  $\mathbb{F}_q$ .

In this case, Eq. (4.4) holds and the projectivization  $\mathbb{P}_r$  has

$$\#\mathbb{P}_r = q^2 + q + 1 - (q + 2) = q^2 - 1,$$

unless there is a  $m \in \mathbb{F}_q$  such that  $[-(m + s)s : m : 1] = [s^2 : s : 1] \Leftrightarrow 3s^2 = 0$ , which is satisfied only when  $q = 3^k$ , in which case  $\#\mathbb{P}_r = q^2$ . This result is also confirmed by the following statement, obtained analogously to Theorem 3.3.

**Theorem 5.5.** If  $q \not\equiv 1 \pmod{3}$ ,  $q \neq 3$  and  $r \in \mathbb{F}_q^\times$ , then there is the group isomorphism

$$\begin{aligned} (\mathbb{P}_r, \odot_r) &\cong \mathbb{F}_{q^2}^\times, \\ [l : m : n] = \{\lambda[l + mt + nt^2] \mid \lambda \neq 0\} &\longmapsto \left( \frac{l - s^2n}{l + sm + s^2n}, \frac{m - sn}{l + sm + s^2n} \right), \\ [s^2(1 - sv + 2u) : s(1 + 2sv - u) : 1 - sv - u] &\longleftarrow (u, v). \end{aligned}$$

Therefore,  $(\mathbb{P}_r, \odot_r)$  is a cyclic group of order  $q^2 - 1$ .

*Proof.* Given  $s$  cubic root of  $r$  in  $\mathbb{F}_q$ ,  $t^3 - r$  is reducible over  $\mathbb{F}_q$  as

$$t^3 - r = (t - s)(t^2 + st + s^2),$$

so that, using the Chinese remainder theorem, there is the ring isomorphism

$$\begin{aligned} \mathcal{R}_r &= \mathbb{F}_q[t]/\langle t^3 - r \rangle \xrightarrow{\sim} \mathbb{F}_q[t]/\langle t - s \rangle \times \mathbb{F}_q[t]/\langle t^2 + st + s^2 \rangle, \\ x + yt + zt^2 &\mapsto (x + sy + s^2z, x - s^2z + (y - sz)t). \end{aligned}$$

In addition,  $\mathbb{F}_q[t]/\langle t - s \rangle \cong \mathbb{F}_q$  and  $\mathbb{F}_q[t]/\langle t^2 + st + s^2 \rangle \cong \mathbb{F}_{q^2}$ . When passing to the quotients, we obtain that

$$(\mathbb{P}_r, \odot_r) = \mathcal{R}_r^{\odot_r} / \mathbb{F}_q^\times \cong (\mathbb{F}_q^\times \times \mathbb{F}_{q^2}^\times) / \mathbb{F}_q^\times \cong \mathbb{F}_{q^2}^\times,$$

through the map in the statement. This confirms that  $(\mathbb{P}_r, \odot_r)$  is a cyclic group of order  $q^2 - 1$ .  $\square$

The relation with the Pell cubic when  $p \neq 3$  is given by the following result.

**Theorem 5.6.** If  $q \equiv 2 \pmod{3}$  and  $r \in \mathbb{F}_q^\times$ , then the following map is a group isomorphism

$$\begin{aligned} \psi_3 : (\mathbb{P}_r, \odot_r) &\xrightarrow{\sim} (\mathcal{C}_r, \odot_r), \\ [l : m : n] &\mapsto N_r(l, m, n)^{\lfloor q/3 \rfloor} (l, m, n) \end{aligned}$$

and its inverse is

$$\begin{aligned} \psi_3^{-1} : (\mathcal{C}_r, \odot_r) &\xrightarrow{\sim} (\mathbb{P}_r, \odot_r), \\ (1, 0, 0) &\mapsto [1 : 0 : 0], \\ (x, y, 0) &\mapsto [x/y : 1 : 0], \\ (x, y, z) &\mapsto [x/z : y/z : 1]. \end{aligned}$$

*Proof.* In order for  $\psi_3$  to be a group isomorphism, it must be:

- well defined: if  $[l : m : n] = [l' : m' : n'] \in \mathbb{P}_r$ , then there is  $\lambda \in \mathbb{F}^\times$  such that  $[l' : m' : n'] = [\lambda l : \lambda m : \lambda n]$ , and since  $\lfloor q/3 \rfloor = (q - 2)/3$

$$\begin{aligned} N_r(\lambda l, \lambda m, \lambda n)^{\frac{q-2}{3}} (\lambda l, \lambda m, \lambda n) &= (\lambda^3 N_r(l, m, n))^{\frac{q-2}{3}} \lambda (l, m, n) \\ &= \lambda^{q-1} N_r(l, m, n)^{\frac{q-2}{3}} (l, m, n), \end{aligned}$$

therefore  $\psi_3$  is well defined. In addition,  $\psi_3(\mathbb{P}_r) \subseteq \mathcal{C}_r$  because

$$\begin{aligned} N_r(\psi_3([l : m : n])) &= N_r(l, m, n)^{q-2} N_r(l, m, n) \\ &= N_r(l, m, n)^{q-1} = 1; \end{aligned}$$

- a group homomorphism: given  $[l_1 : m_1 : n_1], [l_2 : m_2 : n_2] \in \mathbb{P}_r$ , by denoting  $[l : m : n] = [l_1 : m_1 : n_1] \odot_r [l_2 : m_2 : n_2]$ , we have

$$\begin{aligned} \psi_3([l : m : n]) &= N_r(l, m, n)^{\lfloor q/3 \rfloor} (l, m, n) \\ &= N_r(l_1, m_1, n_1)^{\lfloor q/3 \rfloor} N_r(l_2, m_2, n_2)^{\lfloor q/3 \rfloor} \\ &\quad (l_1, m_1, n_1) \odot_r (l_2, m_2, n_2) \\ &= \psi_3([l_1 : m_1 : n_1]) \odot_r \psi_3([l_2 : m_2 : n_2]); \end{aligned}$$

- injective: for any  $[l : m : n] \in \mathbb{P}_r$ ,  $N_r(l, m, n) \neq 0$  and

$$\begin{aligned} \psi_3([l : m : n]) = (1, 0, 0) &\Leftrightarrow \begin{cases} N_r(l, m, n)^{\lfloor q/3 \rfloor} l = 1, \\ N_r(l, m, n)^{\lfloor q/3 \rfloor} m = 0, \\ N_r(l, m, n)^{\lfloor q/3 \rfloor} n = 0 \end{cases} \\ &\Leftrightarrow \begin{cases} (l^3)^{(q-2)/3} l = 1, \\ m = 0, \\ n = 0, \end{cases} \\ &\Leftrightarrow [l : m : n] = [1 : 0 : 0]; \end{aligned}$$

- surjective: we observe that an entry of  $\psi_3([l : m : n])$  is zero if and only if the corresponding entry of  $[l : m : n]$  is null. Thus, given a point  $(x, y, z) \in \mathcal{C}_r$ , have three cases:

- if  $y = z = 0$ , then from the equation of the Pell cubic we have  $x^3 = 1$ , that admits only the solution  $x = 1$ . Therefore  $(1, 0, 0)$  is the only point of  $\mathcal{C}_r$  with  $y = z = 0$ , and it can be obtained through  $\psi_3$  only from the identity  $[1 : 0 : 0]$  of  $\mathbb{P}_r$ ;
- if  $z = 0$  but  $y \neq 0$ , then the preimage of  $(x, y, 0)$  must have canonical representative  $[l : 1 : 0]$  with

$$\begin{cases} x = (l^3 + r)^{\lfloor q/3 \rfloor} l, \\ y = (l^3 + r)^{\lfloor q/3 \rfloor} \end{cases} \Rightarrow l = \frac{x}{y};$$

- if  $z \neq 0$ , then the preimage of  $(x, y, z)$  must have canonical representative  $[l : m : 1]$  with

$$\begin{cases} x = N_r(l, m, 1)^{\lfloor q/3 \rfloor} l, \\ y = N_r(l, m, 1)^{\lfloor q/3 \rfloor} m, \\ z = N_r(l, m, 1)^{\lfloor q/3 \rfloor} \end{cases} \Rightarrow \begin{cases} l = x/z, \\ m = y/z. \end{cases}$$

In conclusion,  $\psi_3$  is a group isomorphism with the wanted inverse.  $\square$

For sake of completeness, when  $q = p^k$  with  $p = 3$ , with an analogous proof, we obtain the group isomorphism

$$\begin{aligned} \psi'_3 : (\mathbb{P}_r, \odot_r) &\xrightarrow{\sim} (\mathcal{C}_r, \odot_r), \\ [l : m : n] &\longmapsto N_r(l, m, n)^{q/3-1} (l, m, n)^{\odot_r 2}. \end{aligned}$$

Thanks to the group isomorphism  $\psi_3$ , the properties of  $(\mathbb{P}_r, \odot_r)$  are inherited by  $(\mathcal{C}_r, \odot_r)$ , i.e, it is cyclic with  $q^2 - 1$  elements. In addition, it allows to find all the solutions of the cubic Pell equation by simply evaluating  $\psi_3$  over all the elements of  $\mathbb{P}_r$ , which are described explicitly in Eq. (4.4). As in the previous case, the explicit inverse can be used to describe each point of the Pell cubic with two thirds of the size of points in  $\mathbb{F}_q^3$ .

**Example 5.3.** Let us consider  $q = 11$  and  $r = 9$ , which is the cube of 4 in  $\mathbb{F}_{11}$ . Thanks to the previous results we know that the cubic Pell equation

$$x^3 + 9y^3 + 4z^3 + 6xyz \equiv 1 \pmod{11},$$

admits  $q^2 - 1 = 120$  solutions and we are able to find all of them evaluating

$$\begin{aligned}\psi_3([l : m : 1]), \quad \forall m \in \mathbb{F}_{11}, l \in \mathbb{F}_{11} \setminus \{-4m + 5\}, (l, m) \neq (5, 4), \\ \psi_3([l : 1 : 0]), \quad \forall l \in \mathbb{F}_{11} \setminus \{-4\}, \\ \psi_3([1 : 0 : 0]) = (1, 0, 0).\end{aligned}$$

For instance, for finding a random solution of the cubic Pell equation, we can take a random  $m \in \mathbb{F}_{11}$ , e.g.,  $m = 2$ , and another element  $l \in \mathbb{F}_{11} \setminus \{8\}$ , e.g.,  $l = 7$ , and evaluate

$$\psi_3([7 : 2 : 1]) = (9, 1, 6).$$

One can check that  $9^3 + 9 \cdot 1^3 + 4 \cdot 6^3 + 6 \cdot 9 \cdot 1 \cdot 6 \equiv 1 \pmod{11}$ .

Similarly, we can take  $l = 3 \neq 7$  and  $[3 : 1 : 0] \in \mathbb{P}_9$ , so that

$$\psi_1([3 : 1 : 0]) = (4, 5, 0),$$

is another solution of the cubic Pell equation.
