ABSTRACT

We present a numerical simulation study at 200 K of *pBn* and *nBn* Hg_{1-x}Cd_xTe barrier detectors, focused on the effects of the composition profile on the *J-V* characteristics in dark. Considering a conventional barrier detector structure with three regions (absorber, barrier, cap), we discuss how the *J-V* characteristics are affected by the steepness of the cap/barrier and barrier/absorber interfaces, especially in the *nBn* configuration.

Keywords: Infrared Detector, Barrier Detector, HgCdTe, graded HgCdTe composition profile

1. INTRODUCTION

Mercury cadmium telluride (Hg_{1-x}Cd_xTe) is a ternary alloy semiconductor with electrical and optical properties suited for the entire spectrum of infrared (IR) applications. Hg_{1-x}Cd_xTe is one of the most employed semiconductors in a wide variety of IR devices, such as photodetectors, photoconductors, and complex structures like focal plane arrays (FPAs) for imaging.¹⁻⁶ Those applications are possible thanks to Hg_{1-x}Cd_xTe properties as its bandgap tunability and optical parameters that enable the fabrication of graded mole fraction profiles and high quantum efficiency devices.^{7,8}

Conventional Hg_{1-x}Cd_xTe detectors require cryogenic temperatures for IR detection to reduce the dark current density, J_{dark} , to acceptable values. The main contributions to the dark current are Auger recombination (an intrinsic mechanism) and Shockley-Read-Hall recombination (SRH, an extrinsic mechanism dependent on the defect density).⁹⁻¹²

Recently, new devices such as barrier detectors have been designed to reduce the dark current associated with SRH recombination in depleted regions without blocking the photocurrents.¹³ Therefore, Hg_{1-x}Cd_xTe barrier detectors have emerged as a possible solution to minimize dark current with negligible Auger generation-recombination and reduced impact of SRH.¹⁴ Moreover, Hg_{1-x}Cd_xTe barrier detectors can operate at higher temperatures with respect to traditional detectors, thus overcoming the need of cryogenic temperatures.

In this work, we investigate the effects on the current-voltage *J-V* characteristics in dark of graded profiles at the barrier interface with the absorber and the cap layers for both *nBn* and *pBn* Hg_{1-x}Cd_xTe barrier detectors. The simulated detectors feature a linearly graded interface across the barrier layer. We compare their *J-V* characteristics against the one of an ideally abrupt composition profile.

2. GEOMETRY AND MODELING

The geometry of the barrier detector we studied consists of three layers, i.e., absorber, barrier, and cap, as illustrated in Fig. 1 (left).

The relevant quantities used in the geometry are summarized in Table 1. The absorber layer, with a thickness of $d_{\text{abs}} = 5 \mu\text{m}$, presents a constant mole fraction profile of $x = 0.3$. The barrier has a thickness $d_{\text{barr}} = 0.5 \mu\text{m}$ and a mole fraction of $x = 0.6$. The cap layer mole fractions is $x = 0.4$ in the pBn case and $x = 0.3$ in the nBn configuration. In Fig. 1 (right), the mole fraction composition profile across the barrier layer is shown for the pBn abrupt configuration. In the study, the extension of the graded profile between absorber and barrier (A/B, $d_{\text{grad,A/B}}$) and between barrier and cap (B/C, $d_{\text{grad,B/C}}$) determines the total barrier thickness, reducing d_{barr} .

The doping profile presents abrupt transitions between the different layers. The absorber is doped $N_{\text{abs}} = 5 \times 10^{15} \text{cm}^{-3}$, the barrier $N_{\text{barr}} = 1 \times 10^{15} \text{cm}^{-3}$ for the pBn case and $N_{\text{barr}} = 1 \times 10^{14} \text{cm}^{-3}$ for the nBn case, and the cap $N_{\text{cap}} = 1 \times 10^{15} \text{cm}^{-3}$. The absorber is n -doped in both configurations, while the barrier, as well as the cap layer, is p -doped for the pBn case and n -doped for the nBn case. High n -doping concentration is present in the contact region of the absorber.

The numerical simulation framework is based on a quasi-1D model, and it implements drift-diffusion equations. The model includes Fermi statistics and incomplete ionization. SRH, radiative and Auger generation-recombination mechanisms are included in the simulation as they are the main mechanisms that dominate the dark current. All simulations use 200 K as a reference temperature.

| Device | Layer | Dopant concentration | Geometrical Quantities | | Mole Fraction |
|--------|----------|-----------------------------------|------------------------|-------------------|---------------|
| pBn | Absorber | $5 \times 10^{15} \text{cm}^{-3}$ | d_{abs} | $5 \mu\text{m}$ | 0.3 |
| | Barrier | $1 \times 10^{15} \text{cm}^{-3}$ | d_{barr} | $0.5 \mu\text{m}$ | 0.6 |
| | Cap | $1 \times 10^{15} \text{cm}^{-3}$ | d_{cap} | $0.3 \mu\text{m}$ | 0.4 |
| | | | $d_{\text{grad,A/B}}$ | $0 \mu\text{m}$ | |
| nBn | Absorber | $5 \times 10^{15} \text{cm}^{-3}$ | d_{abs} | $5 \mu\text{m}$ | 0.3 |
| | Barrier | $1 \times 10^{14} \text{cm}^{-3}$ | d_{barr} | $0.5 \mu\text{m}$ | 0.6 |
| | Cap | $1 \times 10^{15} \text{cm}^{-3}$ | d_{cap} | $0.3 \mu\text{m}$ | 0.3 |
| | | | $d_{\text{grad,A/B}}$ | $0.2 \mu\text{m}$ | |

3. RESULTS AND DISCUSSION

This Section presents and discusses the results obtained from our numerical investigation on the pBn and nBn configurations. The aim is to identify how graded mole fraction profiles impact the equilibrium band diagram, the J - V characteristics, and the SRH rate.

First, Fig. 2 shows the equilibrium band diagrams of the pBn and the nBn configurations. The pBn configuration exhibits a valence band offset between the absorber and the barrier of approximately 45 meV, while the nBn configuration shows a valence band offset close to 80 meV. The pBn configuration has most of the barrier falling in the conduction band, thanks to the p -doped barrier profile. On the contrary, nBn configuration presents an almost un-doped barrier to minimize the equilibrium valence band offset. These differences influence the J - V characteristic, particularly at lower biases. The effect in the J - V characteristics can be seen in Fig. 3 and Fig. 4 in the $[0, -0.2]$ V bias range.

Figure 2. Equilibrium band diagram for the pBn (left) and nBn (right) configurations.

Fig. 3 reports the pBn J - V characteristic and compares the total and SRH recombination rates in the cap layer at the peak value. A dark current plateau determined by the hole current density is present in the reverse bias range of 0.1 up to 1 V for $d_{\text{grad,B/C}} = 0$ nm. When increasing $d_{\text{grad,B/C}}$ to 200 nm, the bias range corresponding to the dark current plateau shrinks from 0.1 to 0.5 V. The variation in the total current is due to the increase in the electron current density. The same increase is present in the SRH recombination rate. The reduction of the reverse bias range is compatible with the shift of the SRH generation mechanism as the $d_{\text{grad,B/C}}$ is reduced. SRH is, in fact, the main generation mechanism and coincides with the total generation rate. For $d_{\text{grad,B/C}} = 0$ nm, the SRH generation exceeds $1 \times 10^{16} \text{ cm}^{-3}\text{s}^{-1}$ above 1 V reverse bias. For $d_{\text{grad,B/C}} = 100$ nm and $d_{\text{grad,B/C}} = 200$ nm, the generation exceeds $1 \times 10^{16} \text{ cm}^{-3}\text{s}^{-1}$ above 0.7 V and 0.6 V reverse bias respectively. All the considered generation rates, as well as the current density, tend to saturate for high reverse bias applied.

Fig. 4 reports the nBn J - V characteristic and the total and SRH generation-recombination profiles, as with the pBn configuration. In this nBn configuration, only the case with an abrupt transition between the barrier and the cap shows a dark current plateau. The other grading profiles allow the flow of electron current density that prevents the intended behavior of the devices. When $d_{\text{grad,B/C}} = 0$ nm, no SRH generation is present, and the total recombination rate is equal to the SRH recombination.

In conclusion, numerical simulations on barrier detectors show the sensitivity of J - V characteristics with respect to the linear and abrupt composition profile. The nBn configuration has the most pronounced sensitivity to the grading profile, and only the abrupt configuration has the intended behavior. The pBn configurations are

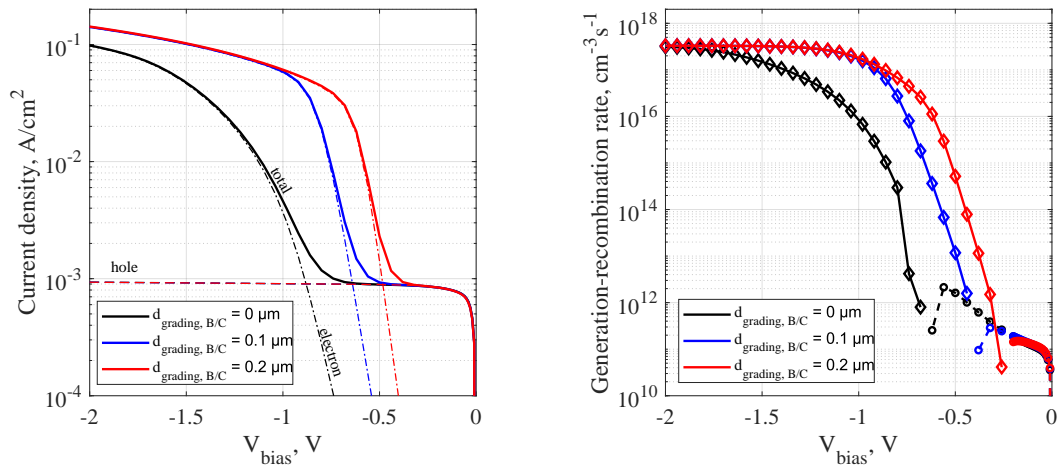

Figure 3. *pBn* configuration with different $d_{\text{grad, B/C}}$ values. J - V characteristics (left) and SRH and total generation-recombination rates within the cap layer at $y = 6.15 \mu\text{m}$ as a function of the applied bias (right). In the J - V curves, the hole current is indicated by a dashed line, the electron current by a dotted line, and the total current by a solid line. In the SRH plot, SRH recombination is indicated by a dashed line, SRH generation by a solid line, total recombination by circular markers, and total generation by diamond markers.

Figure 4. *nBn* configuration with different $d_{\text{grad, B/C}}$ values. J - V characteristics (left) and SRH and total generation-recombination rates within the cap layer at $y = 6.15 \mu\text{m}$ as a function of the applied bias (right). In the J - V curves, the hole current is indicated by a dashed line, the electron current by a dotted line, and the total current by a solid line. In the SRH plot, SRH recombination is indicated by a dashed line, SRH generation by a solid line, total recombination by circular markers, and total generation by diamond markers.

less sensitive to the different grading profiles, but the shrink of the dark current plateau allows only a reduced set of applied biases. The simulations suggest possible graded mole fraction profile optimization of $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ barrier detectors, with the potential of enhancing the efficacy of barrier detectors by controlling dark current and minimizing SRH effects.
