Abstract

50 This work has focused on *surface engineering* coupled with brazing to join SiC_fSiC 52 composites and to improve t $\frac{52}{53}$ composites and to improve the joint strength. The surface engineering was carried out 55 through the Selective Thermal Removal (STR) of SiC fibres from a SiC_fSiC composite to obtain "brush-like" surfaces; the modified composites were then joined by means of 58 resolution of the state state an AgCuTi braze alloy. In order to investigate whether a "brush-like" interface could

 enhance the mechanical strength of the joint by increasing mechanical interlocking with $\frac{3}{100}$ the brezing elloy et the miero $\frac{3}{4}$ the brazing alloy at the micron scale, the joints were tested with and without surface $5₅$ engineering by means of single lap offset under compression.

 The treatment to form a rough $\frac{8}{9}$ The treatment to form a roughened surface suitable for mechanical keying of the braze metal led to an improved ductility of the joint; the fracture surfaces demonstrated that the proposed method is promising, even though the treatment damages locally the 16 composite.

Example compris motivity EVERE 21 Keywords: ceramic matrix composites; joining; surface engineering; brazing.

$\frac{25}{26}$ 1. Introduction **1. Introduction**

 Ceramic Matrix Composites (CMCs) are generally composed of straight or woven ceramic fibres embedded in a ceramic matrix with a weak bond between them, a process **Commonweal** contract of the contract of th 32 and 1 in 1 in 1 c ³²/₃₃ that leads to an improved fracture toughness of the composites compared to the matrix or to fibre materials. Because of their superior thermomechanical properties, CMCs $1 \tanh 1$ 67 64 64 $\frac{38}{38}$ based on a SiC matrix reinforced with silicon carbide fibres (SiC_f/SiC) are materials of great interest for many applications, ranging from the aerospace [1,2] to the nuclear field [3.5] which require ex $^{42}_{43}$ field [3-5], which require extremely high temperature stability and damage tolerance. SiC_{f/}SiC are currently being used as thermo-structural materials in different components such as aircraft $\frac{47}{48}$ components, such as aircraft brakes, body flaps, leading edges, heat exchanger components, gas turbines for power plants, thermal protection systems for space vehicles and the inner walls of plasma chambers of nuclear fusion reactors [6]. **11** 11 ⁵⁴₅₅ However, in many cases, their use depends to a great extent on their ability to be joined and integrated, since the manufacturing of these materials as large components or complex geometries is difficult and expensive. The study and development of reliable

 joining methods to assemble CMC as large components in complex structures is a $\frac{3}{2}$ exiting $\frac{1}{2}$ issue for a wider use $\frac{3}{2}$ $\frac{3}{4}$ critical issue for a wider use of these materials.

 The surface engineering of CMC has attracted a great deal of attention from the $8 \qquad \qquad$ scientific community as it rep $\frac{8}{9}$ scientific community as it represents a smart and still unexplored technology that can be used to improve the mechanical performances of CMC joints. The design of interfaces coupled with suitable joining materials and joining technologies are key parameters in $\qquad \qquad \qquad$ $\qquad \qquad$ \qquad $\qquad \qquad$ \qquad $\qquad \qquad$ \qquad \q ¹⁵
manufacturing, especially for ceramic matrix composite-based components. In a previous work [7], we proposed a technique based on the Selective Thermal Removal 20 (CTD) of SiC fibres from Si 21 (σ IN) of SIC flores from SP (STR) of SiC fibres from SiCf/SiC composites. This process leads to a micro-sized - that is able to enhance the specific surface of SiCf/SiC. It was 25 demonstrated that the specif $^{25}_{26}$ demonstrated that the specific surface of SiC_f/SiC significantly increased (~ 90%) when fibres were removed parallel and perpendicular to the composite surface.

³⁰ In [7], the effect of the STR process on the composite surface was discussed from the \ldots \ldots \ldots \ldots \ldots 11 12 12 33 morphological point of view and wetting tests, using a AgCuTi brazing alloy, on as- received and modified SiC_f/SiC were performed. In the present work, starting from ³⁶ those promising results, experimental parameters have been transferred from wetting test to joining process and adhesion issues are presented. Surface modified SiC_fSiC ioined samples have been m ⁴²/₄₃ joined samples have been manufactured and their microstructure studied. In order to assess the effectiveness of the STR process, mechanical tests (single-lap offset under compression) have been con ^{4/} compression) have been conducted on STR modified SiC_f/SiC joined by brazing and the results have been compared with those of reference SiC_f SiC joints (obtained with as- received SiC_f/SiC). Furthermore, the mechanical strength of SiC_f/SiC after STR has been measured to verify the detrimental effects of the surface engineering process on the SiC-based composite itself.

2. Materials and methods

 $\frac{3}{2}$ Koromon® SiC SiC somples $\frac{3}{4}$ Keraman® SiC_{f/}SiC samples supplied by MT Aerospace (Germany) were used for the $5₅$ experimental work. The composites were manufactured at MT Aerospace, Germany, $8 \qquad \qquad$ using the standard gradient C $\frac{8}{9}$ using the standard gradient Chemical Vapour Infiltration (CVI) process and supplied as 11 rectangular shaped samples; they contained Tyranno ® S grade 1.6 K (Ube Industries, Tokyo, Japan) fibres coated with a thin C layer. SiC_f/SiC has a thermal expansion $\qquad \qquad$ \qquad $\qquad \qquad$ \qquad $cc \cdot \sqrt{64 \cdot 10^{-6} \text{ Hz}^{-1}}$ $^{15}_{16}$ coefficient of 4×10^{-6} K⁻¹. K^{-1} . .

18 All the SiC_fSiC showed pores between the fabric layers and some cracks on the $\frac{20}{21}$ surface. Surface.

23 Before brazing, the SiC_{f/}SiC were cut into 5 mm× 5 mm× 2 mm slabs and were then 25 mrocessed at 1450° C for 2 h $^{25}_{26}$ processed at 1450°C for 2 hours under flowing Ar in a tubular oven (according to the STR process described in [7]). The brazing alloy used to join the CMC was a $^{30}_{31}$ commercial AgCuTi alloy (CB4, Degussa, Germany) in the form of 100 μ m thick foils.
 $^{32}_{33}$ This alloy consists of eutectic Ag-Cu activated with 3 wt. % of Ti (nominal π $\frac{1}{2}$ $\frac{1}{2}$ 33 I has alloy consists of eutect. composition: Ag: 57.7, Cu: 36.8, Ti: 5.5 at.%) and belongs to a family of braze media and $\frac{1}{2}$ and $\$ $\frac{38}{38}$ that are commonly used for mid-temperature joining processes; its melting range is 780- 40 805 °C and it has an optimal brazing temperature in the 850-950 °C range. The braze foil was sandwiched between ⁴²₄₃ foil was sandwiched between composite blocks and this assembly was introduced into an alumina tubular furnace set at 850 °C, held at this temperature for 30 min and then cooled down at a rate of 5 $^{\circ}$ ⁴⁷ cooled down at a rate of 5 °C·min⁻¹. During the process, a vacuum lower than $5 \cdot 10^{-4}$ Pa was maintained by means of a turbomolecular pump; no external load was necessary as adhesion was assured by the capillary forces of the liquid which pulled the surfaces together.

 The SiC_{f/}SiC and joined samples were characterised before and after the STR process 59 voing Eight Emission Second using Field Emission Scanning Electron Microscopy (FESEM- ZEISS Supra 40) with

 an Energy Dispersive Spectroscopy (EDS- SW9100 EDAX) detector and scanning $\frac{3}{2}$ electron microscopy (SEM m $\frac{3}{4}$ electron microscopy (SEM, model: LEO 1450 VP) with an electron microprobe (EDS) $5 - 5$ (Oxford Instruments, 7353 model with Oxford-INCA software v. 4.07, type of detector: $\frac{8}{2}$ Si(Li)). $\mathcal{O}(\mathbf{L}^2)$

 Investigation and structural analysis of the interfacial phases were carried out using Transmission Electron Microscope (TEM) JEOL 2100F UHR operated at 200kV. Image 15 (a) $\frac{1}{1}$ (b) $\frac{1}{1}$ (c) $\frac{1$ ¹⁶ characterization was done in scanning/transmission mode employing bright field detector, in order to utilize mass-thickness contrast for enhancing the distinction of 20 agos with different stamps areas with different atomic number and to avoid undesirable effects of dynamical diffraction. In this mode, EDS analyses were performed by means of detector with 25 $\cos\theta$ ervetal size 80 mm² (Oxford 25 crystal size 80 mm² (Oxford Instruments, Xmax80, INCA software). Phase identification was confirmed by Selected Area Electron Diffraction (SAED) technique. For processing of obtained diffraction patterns licensed sofwares were used (Gatan Digital Micrograph **September 21 September 2016** 1.32 FPR $1 \cdot 1 \cdot 2 \cdot 3 \cdot 11$ ³²/₃₃ and CMPR database). Calibration of digital camera in reciprocal space was set on MoO3 monocrystal standard.

 This f_{c} is f_{c} in f_{c} ³⁶₃₈ Thin foils for purposes of TEM observations were prepared using standard preparation methods including cutting, grinding, polishing, dimpling and final step of the thinning 42 resolute west done by ion $^{42}_{43}$ procedure was done by ion milling (PIPS Model 691 Gatan) operated at 4.5 kV with ion-beam angles of 4° and 3°.

 Complementary phases anal $\frac{47}{48}$ Complementary phases analysis was carried out by X-ray diffraction (XRD, X'Pert Pro 50 MRD, Panalytical, Cu K_a radiation, with the aid of the X-Pert High Score software) and identified with JCPDS files.

 The shear strength of the joined samples (at least 4 as-received SiC_f/SiC joints and STR SiC_{f/}SiC joints) was evaluated using the single lap offset (SLO) test under compression 59 of noon tomporative accord ⁵⁵₆₀ at room temperature, according to a method adapted from ASTM D905-08 (universal

 testing machine SINTEC D/10) [8]; the crosshead speed was 0.5 mm/min. The 3 movimum force wes recorded $\frac{3}{4}$ maximum force was recorded and the shear strength was calculated by dividing the $5 - 5$ maximum force by the joining area.

 The size of the single lap off-⁸ The size of the single lap off-set shear tests for brazed samples was 10 mm \times 3 mm \times 4 10 11 11 11 220 $\frac{10}{11}$ mm with a joined area of 30 mm². 11 mm with a joined area of 30 mm².

12

The SiC_f/SiC samples were subjected to 3-point bending tests (v= 0.5 mm/min; span=

 10 $\sqrt{11}$ $\sqrt{9}$ $\frac{16}{16}$ 40 mm), according to ASTM standard C1341-13 [9], at room temperature before and 18 after the STR treatment. The composite size was $3 \text{ mm} \times 4 \text{ mm} \times 45 \text{ mm}$. The fracture 20 auxforces of the exercise area ²⁰₂₁ surfaces of the specimens were investigated after mechanical characterization by means of SEM/FESEM.

3. Results and discussion **CV Expansion and discussed**

$32 \qquad \qquad 31 \qquad \qquad 32 \qquad \qquad 33$ 3.1 Surface modification and joining

³⁵ The STR process was carried out on the SiC_{f/}SiC samples at 1450 °C for 2 hours to The STR process was carried out on the SiC_{f/}SiC samples at 1450°C for 2 hours to
36
37
38 **obtain "brush-like" surfaces** [7]. The appearance of the modified surface is shown in Figure 1; the SiC fibres were partially and homogeneously removed from the composite 42 surface and pores and data $\frac{42}{43}$ surface, and pores and detached areas formed at the fibre/matrix interface. The presence of silica microwires is evident on the fibre surface (Figure 1 d) and inset e)), both on the fibre cross-sectional area (as $\frac{47}{48}$ fibre cross-sectional area (as shown in the micrographs) and on the external part of the fibres parallel to the treated surface.

 When exposed to temperatures above 1000°C, the fibres used as reinforcement in the 53 and $\frac{1}{1}$ and $\frac{1$ **G'OCO'C** 1' 1' $55⁴$ SiCf/SiC are subjected to a thermal degradation, as discussed in [7]. The thermal degradation occurs both at the end of the fibres and on the body of the fibres, at least on

 the part of the body exposed to STR atmosphere. In that sense, STR also acts on fibres $\frac{3}{2}$ norellal to the joining surface $\frac{3}{4}$ parallel to the joining surface and on the overall mechanical properties of the composite. $5 - 5$ 6 The modified SiC_fSiC surfaces have been joined using a AgCuTi brazing alloy; the $8 \sim 10^{10}$ in $\frac{1}{2}$ in $\frac{1}{2}$ are $\frac{1}{2}$ and $\frac{1}{2}$ in $\frac{1}{2}$ and $\frac{1}{2}$ in $\frac{1}{2}$ and $\frac{1}{2}$ are $\frac{1}{2}$ and $\frac{1}{2}$ and $\frac{1}{2}$ are $\frac{1}{2}$ and $\frac{1}{2}$ are $\frac{1}{2}$ and $\frac{1}{2}$ ar $\frac{8}{9}$ joining process, carried out in the present work, is based on the results of the wetting tests [7]. The proof of concept of the STR modification surface technique to implement a joining process has been carried out through the morphological investigation of the 9 01 15 and \mathbf{r} and \mathbf{r} $\frac{16}{16}$ cross-section of the joints; Figures 2 a and b show an example of an SiC_f/SiC - AgCuTi - SiC_f/SiC joint.

20 Deth types of compositor (or $^{20}_{21}$ Both types of composites (as-received (Figure 3) and STR treated (Figure 4) SiC_f/SiC) showed the presence of sound joints with the brazing alloy, which was well distributed along the whole joint and ha $\frac{25}{26}$ along the whole joint and had infiltrated into the pores and cracks, as can clearly be observed in the microstructures in Figures 3 and 4. The microstructures of the joint in ³⁰ Figure 3 a-c show that a sub-micrometric Ti-rich layer has formed at the interface and it $\frac{33}{33}$ is visible in the higher magnification figure (inset c). The wetting tests performed by the authors [7] showed that the braze perfectly spread on the SiC_f/SiC surfaces, filling all $\frac{38}{38}$ the cavities and gaps introduced by STR. The present paper reports on the experimental activity carried out to verify the beneficial effect of STR on joints manufacturing. The thermal treatment atched the thermal treatment etched the fibers not only at their top but also on their side, which in 45 turn leads to a micro-sized "brush-like" structure on both the facing surfaces of the joints. 48 Johnston

 50 An SEM cross section of an STR SiC $_f$ SiC joint is shown in Figure 4 for comparison purposes: the brazing alloy has infiltrated the composite surface along the macro- 11 0 1 54 porosities, in the same way as for the as-received SiC_f/SiC, but in this case the brazing 57 alloy has penetrated for $\sim 10 \mu \text{m}$ and infiltrated the gaps obtained by the partial removal of fibres thus of themsel $\lim_{x \to 0}$ $\frac{60}{60}$ of fibres, thus a "brush-like" joint has formed with interlocked joining materials (Figure

 $5 - 5$ The interfacial composition (see Table 1) was similar for the two types of joints. In order to improve the reliab $\frac{8}{9}$ In order to improve the reliability of data from SEM-EDS, the thin Ti-rich layer was analysed by TEM to further identify the interfacial products. Figure 5 shows high- magnification images of the interface and SAED patterns identification of the resulting $\overline{15}$ $\overline{1}$ $\frac{16}{16}$ phases: going from SiC_f/SiC towards the brazing alloy, a ~400nm thick layer formed 18 mostly of TiC nanograins, and a 250 nm thick Ti₅Si₃ layer were detected.

 $\frac{1}{2}$ $\frac{1}{2}$ 20 In the case of an untreated SiC_f/SiC surface (Figure 3), the Ti-rich layer is evident along the whole joint interface and it follows the surface profile (see Figure 3 c). In the case of 25 an STR SiC_eSiC joint (Figure an STR SiC_f/SiC joint (Figure 4), the Ti-rich layer follows the profile of the fibres that had partially been removed by means of STR (Figure 4 b,c) and the gap between the ³⁰ fibre and the matrix formed by the thermal selective process. The reaction formed Ti 31 horses and the manning resince $32 \qquad \qquad \ldots$ rich layer was continuous and homogenous, which led to braze wettability on the surface. This layer followed the profile of the selective etched fibres without obstructing $\frac{38}{38}$ the cavities, but allowed the molten braze to penetrate. In this way, continuous infiltration coupled with good wettability were achieved. The formation of this 42 transition layer at the interfa transition layer at the interface is considered a key factor for ceramic/braze joint 45 strength. In the case of the SiC_fSiC samples, this transition layer was developed on a larger surface thus a larger $\frac{47}{48}$ larger surface, thus a larger contact area was made available for the adhesion between the brazing alloy and the SiC_f/SiC and a gradual CTE (coefficient of thermal expansion) change took place from the brazing alloy to the composite along the CMC porosities. and 53 54 TH CITY C.1 : 1 The CTEs of the interlayer phases were 18.5 and 8.82 x 10^{-6} /°C for the AgCuTi and $T_{13}SiC_2$, respectively, while the CTE of $T_{15}Si_3C_x$ was assumed equal to that of $T_{15}Si_{37}$ 59 $\qquad \qquad \text{as the TiCl, where } \qquad \text{as a constant.}$ $T_{13}SiC_2$, respectively, while the CTE of $T_{15}Si_3C_x$ was assumed equal to that of $T_{15}Si_{35}$
 $T_{15}Si_2C_x$ as the $T_{15}Si_3C_x$ phase is a solid solution that contains only a small percentage of C.

 Ti5Si3 exhibits large CTE anisotropy: 6.11 (basal plane) or 16.62 (c-plane) [10]. In $\frac{3}{3}$ addition thermal migmetable $\frac{3}{4}$ addition, thermal mismatch may be accommodated for by the relatively good plasticity $5 - 5$ of the Ag-Cu braze material [11]. This morphology of the interface in the STR samples ⁸ *s aromotes* bonding *provided* t $\frac{8}{9}$ promotes bonding, provided the interfacial roughness of the treated surface does not hamper the spread of brazing and physical contact.

$\frac{16}{16}$ 3.2 Mechanical characterization

18 The SiC_fSiC samples were subjected to 3-point bending tests before and after the STR 20 tractment in endemte essessi treatment in order to assess the possible detrimental effect of the process $(1450^{\circ}C, 2$ hours, Ar atmosphere) on the mechanical properties of the composite. The as-received SiC_eSiC average flexural str 25 SiC_f/SiC average flexural strength was 576±32 MPa, while the SiC_f/SiC after STR 28 showed an average flexural 30 showed an average flexural strength of 387±67 MPa.

²⁹

Figure 6 shows the representative flexural strength load -displacement curves of the

1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1.8 1. and 32 $\overline{S_3}$ SiC_{f/}SiC at room temperature, before and after the STR treatment. The STR caused a decrease in the composites flexural strength of about 30%, due to the fibre and $\frac{38}{38}$ fibre/matrix interface degradation [7]. The load-displacement curves exhibit the typical "plastic-like" behaviour that occurs in CMCs because of the toughening mechanisms of 42 crack bridging deflection and erack bridging, deflection and slippage at the interface between the fibres and matrix; 45 this trend was observed in both of the tested SiC_f/SiC types, that is, as-received and STR treated The lower mechanic treated. The lower mechanical strength of the SiC_f/SiC after STR may be ascribed to the partial degradation of the thin carbon layer at the fibre/matrix interface and of the SiC fibres; it has been reported that the residual tensile strength of Tyranno S fibres, after a and $\overline{1}$ 54 1 1 1 1 1 1 1 1 1 1 1 1 2 2 2 \sim 54 1 1 1 1 2 2 2 \sim 6 1 1 1 2 2 2 2 \sim 6 1 1 1 2 2 2 2 \sim 6 1 1 1 2 2 2 2 \sim 6 1 1 1 2 \sim 7 2 \sim 7 1 1 2 \sim 7 2 \sim 7 1 1 2 \sim 7 \sim 7 1 1 2 \sim 7 \sim 7 1 1 2 \sim heat treatment at 1450°C for 1 hour in Ar, is only 20% of the original value [12]. Despite this significant decrease in mechanical strength of the fibres [13, 14], the 59 composite netained about 70 composite retained about 70% of its original strength after STR. The present

 experimental activity is still underway to confine the STR process to the composite $\frac{3}{2}$ surface in order to evoid or $\frac{3}{2}$ $\frac{3}{4}$ surface, in order to avoid or significantly reduce the decrease in mechanical strength of $5 - 5$ the whole composite.

 The single lap offset (SI O) to $\frac{8}{9}$ The single lap offset (SLO) test under compression was chosen as the mechanical test $\qquad \qquad$ \qquad $\qquad \qquad$ \qquad \qquad 11 for joined SiC_f/SiC in order to understand whether the STR process was useful to SiC_{f/}SiC to obtain statistically relevant results, and it can be useful to compare different $\frac{16}{16}$ joining materials and joining processes [15]. The measured shear strength of the joints ¹⁸ produced with the as-received SiC_{f/}SiC showed a value of 21.3 ± 6.5 MPa, while the 20 CTD treated and then igned $^{20}_{21}$ STR treated and then joined SiC_f/SiC resulted in a value of 16.5 \pm 4.5 MPa, which 23 roughly corresponds to a 30% decrease, as already observed for the $\text{SiC}_\text{f}/\text{SiC}$ flexural strength before and after the ²⁵ strength before and after the same heat treatment used for the STR process.

28 The decrease in mechanical strength of the whole SiC_f/SiC after STR does not allow any improvement, if any, to be measured in the lap-shear strength of these joints. $\frac{1}{21}$ $\frac{1}{21}$

 $\sqrt{3}$ $\sqrt{2}$ $\sqrt{2}$ $\sqrt{2}$ $\sqrt{2}$ 33 XRD analysis (Figure7) was carried out on the joint fracture surfaces to detect the interfacial phases and to confirm the EDS and TEM analysis. The pattern shows several $36 \qquad \qquad \frac{1}{1}$ 37 and the same state of the second state of the second state of the second state of the second state of the s phases in good agreement with data obtained by TEM analysis: it put in evidence the formation of Ti5Si3 and TiC (presumably at the interface between the brazing alloy and 42 the composite surface) and $^{42}_{43}$ the composite surface) and Ag and Cu mostly due the brazing alloy infiltration. The SiC/SiC composite substrate is detectable by SiC peaks.

 There is no difference in det $\frac{47}{48}$ There is no difference in detected phases on the fracture surface after the mechanical 49 and $\frac{1}{2}$ and $\frac{1$ tests on the SiC_f/SiC joined samples without STR (Figure 7) and with STR.

⁵² However, the The fracture surface analysis (Figure 8) revealed a promising 55 morphology; as can be observed in Figures 8 a) and b), the as-received SiC_fSiC joint underwent delamination of the composite close to the joined region, with a few spots 59 charrier magnetification showing macro-infiltration of the brazing alloy (already shown in the cross-section in

 Figure 3 a) and a flat fracture surface. On the other hand, the infiltration of the brazing $\frac{3}{2}$ elloy ell eround the fibres in t alloy all around the fibres in the STR joined SiC_f/SiC (Figure 8 d) caused a non-flat $5 - 5$ fracture surface and extensive pull-out of the fibres (Figure 8 c), in agreement with the eross section shown in Figure $\frac{8}{9}$ cross section shown in Figures 4b and c. All this seems to indicate an effective role of **1 1 1 1 1 1 1 1 1** the STR in obtaining a brush-like structure, even though this has not yet been supported ¹³ by a measured increase in the mechanical strength of the joint. A schematic of the α 1 α 1 α $\frac{16}{16}$ fracture path in SiC_f/SiC joints is shown in The fracture path in SiC_f/SiC joints is shown in Figure 9.

17

18 The different failure mechanisms in the SiC_f/SiC joints, with and without the STR

 20 tractment is also evident in treatment, is also evident in Figure 10. The typical load/displacement curves of the 23 SiC_{f/}SiC joints without STR, as tested by means of SLO, show brittle behaviour (Figure 10 full line) On the other k $^{25}_{26}$ 10, full line). On the other hand, the SiC_f/SiC processed with STR and then joined exhibit a load/displacement curve (Figure 10, dotted line) with non-brittle, segmented ³⁰ behaviour that is typical of a composite material; this can be explained by considering \ldots 31 ³² the increased toughness of the joint, due to the formation of a composite joining material at the interface between the infiltrated brazing alloys and the STR SiC_f/SiC. $\qquad \qquad \qquad \qquad \qquad$ $\qquad \qquad \qquad \qquad$ Other activities are currently underway in order to modify the STR process so as to 40 avoid the degradation of all the SiC_fSiC mechanical properties, that is, to confine the thermal removal process at t ⁴²₄₃ thermal removal process at the composite surface.

 Moreover, the stress condition in the braze as in the ceramic composite is clearly dominated by the residual st $\frac{47}{48}$ dominated by the residual stresses. Stress level in the braze can be mitigated by plastic relaxation strain. Contraction of the brazing alloy layer is hindered by the metal cramped with the ceramic in the structured surface layer.

 ⁵⁴₅₅ The ceramic opposes the reduction of the distance of the filled holes, thus leading to compression stresses in the composites. On the other hand, the thermal shrinkage of the coldon in the holes loods to b solder in the holes leads to high tension stresses. As a consequence, the brush-like

 surface can increase the residual stresses at the interface between the metal and the $\frac{3}{2}$ composito $\frac{3}{4}$ composite.

 The tuning of the structuring depth is a key factor in order to have a balance between an $8 \qquad \qquad \text{improved mechanical interval}$ $\frac{8}{9}$ improved mechanical interlocking and a reduction of detrimental stress peaks at the interface.

1 α **1** α $\frac{16}{16}$ 4. Conclusions

 The proposed surface engineering treatment (Selective Thermal Removal, STR) has 20 hear weses fully used to a been successfully used to obtain "brush-like" SiC_f/SiC surfaces.

 The main advantages of this process are (i) modification of the surface, due to a one- 25 step pre-treatment which in $\frac{25}{26}$ step pre-treatment, which increases the surface area and allows the joining material to be mechanically anchored, and (ii) a completely dry and environmental friendly process, in which no hazardous chemicals are used and which, coupled with a high P^{181855} , m which its numerical ³²/₃₃ reproducibility of the process, makes this process attractive for implementation in automatic and production machinery.

 The level 11 CC 0.01 $\frac{38}{38}$ The brush-like SiC_{f/}SiC interface was well infiltrated by the Ag-based brazing alloy, ⁴⁰ and this led to a composite-like fracture surface and a "plastic-like" load/displacement curve after a single lap offse ⁴²
43 curve after a single lap offset test under compression of the joints.

 At this stage of the research, the STR process seems to be effective in increasing the 47 ioint toughness but the treat $\frac{47}{48}$ joint toughness, but the treatment still needs to be modified in order to avoid degradation of the whole SiC_f/SiC. The future experimental activities will focus on a localised and less harsh thermal process, in order to find a good compromise between surface engineering and composite integrity.

Acknowledgments

1 The research leading to these results has received funding from the European Union's 3
Soveth Framework Program $\frac{3}{4}$ Seventh Framework Programme FP7 2007-2013 under grant agreement 609188, within $5 - 5$ the European ADMACOM (Advanced manufacturing routes for metal/composite $8 \qquad \qquad \text{components for a consequence, }$ components for aerospace, www.admacomproject.eu) project.

 11 The authors wish to thank Dr. Peter Tatarko (Institute of Inorganic Chemistry Slovak Academy of Sciences, Bratislava, Slovakia) for his support and helpful $15 \qquad \qquad \ldots$ discussion.

 The authors are also thankful to Joerg Weise and Simon Fecht (Fraunhofer Institute for M orufosturino Technology 20
21 **Manufacturing Technology and Advanced Materials IFAM-Bremen, Germany)** for their support in the discussion of the results.
