Methods. A new exercise machine that allows the execution of chest press and row on upright position (upright press and upright row) has been designed. In order to verify if these methods are applicable to elite athletes, increasing load tests (strength-speed curve) have been made on female athletes of Italian judo and rugby national teams. The study has been made on 14 judo athletes, 6 of them training for Beijing Olympic Games 2008 and 12 of the National Rugby Team; aged 26.7±5.9 for judo, 25.6±1.6 for rugby, weight 62.6±9.7 for judo, 66.1±9.7 for rugby, height 1.85±7.1 for judo, 1.66±.7 for rugby. The aim of this research was to verify the reliability of the test and how it is suitable for elite athletes.

Results. The results prove that either the standing pull or push have a good intra-tester reliability with positive statistical values 1.4% for the pull and 0.97% for the push. Moreover, for the upright press and upright row the data show a good inter-day repeatability with values between -9.1 and +11.4% among different days for upright row and between -9.7 and +7.7% for upright press. We can attest that the measure system used has a good reliability and so it can be applied for the functional evaluation of elite athletes. It is not possible to extend this good reliability to non professional or younger athletes and further studies should be done for this purpose. Moreover, during the tests no athletes showed joint injury or pain.

Conclusions. In sports where you stand and with important contact phases with the opponent it is relevant to propose specific training exercises. In order to achieve a satisfactory reliability and for a good compliance as the athletes report we can suppose to use the measure system suggested for the training planning and control.

The effect on joint mobility after one week training with karate-preparatory exercises vs sport games in children

The aim of the present study was to analyze if the use of specific training vs sport games training has comparable impact on technical gestures and joint mobility in children who practice karate. Hundred-sixty-eight children were randomized in two groups: Karate Game (KG) (n=81) and Sports Game (SG) (n=81). All children have done two workouts a day (one in morning and one in afternoon) for a week. Before and after the training period, they underwent a battery test: throwing of the medicine ball, standing long jump, joint mobility and lateral and frontal jumps. KG group was trained in specific way, considering coordination, balance and joint mobility exercises aspects; SG group was trained playing mini-football and volleyball. After one week of training all subjects were analyzed, showing that the KG group only was improved (throwing of the medicine ball +3%, p=0.05), standing long jump +5.1, p=0.001, joint mobility +1.5%, p=0.001 and lateral/frontal jumps +22.9%, p=0.001, while in the SG group there was significant improvement only in lateral jumps +4.5%, p=0.05. From this study we demonstrated that exercise induces physical improvements but the choice of exercises is important for the optimization of training and the technical development of children oriented towards a specific sport activities.

Comparison of the effects of massage with mineral oil or oozated oil bioperroxidol on blood lactate, stress perceived and heart rate in cyclists

Muscular fatigue is a factor that influence heavily performance of athletes. There is a lack of data about effect of massage with substances "ad hoc". The aim of our research was to investigate the effect of application of oozated oil on some parameters linked to fatigue in cyclists.

30 cyclists male were divided in two groups of 15 (PLO = placebo oil, OZO = oozated Oil). Subjects was submitted in two different session to work protocol that consist in a rectangular test on cyclograpermometer followed by 30' of rest. After the rest athletes performed an incremental test. HR (heart rate), Winux (Watt maxima), RPE (rate of Perceived Exertion) and Lact (Blood Lactate) was measured at the end and after 5' and 10' after the test. In the first session (PLO subjects remained at completely rest after rectangular test (30' rest), in the second session athletes executed a self message (MS) on lower limbs with OZO or PLO during rest.

The meteo-hydrological analysis and the sport performance: which are the connections? The case of the XXI Winter Olympic Games, Vancouver 2010

The main goal of this research is to show how the climatological and meteoroanalysis, relatively to a determinate geographical zone and with reference to a specific period of interest, are able
be used in sport area for the amelioration of the athlete's performance. For this reason it was decided to contextualize the analysis to the competition field of the XXI Winter Olympic Games, held in Turin (Veneto-Lombardia, Italy) in February 2010. The central part of the work consists in the examination of historical series of temperature, precipitation, relative humidity and wind: moreover, the whole data analysis has been completed with the study of climatological phenomenon on different scale, verifying the existence of recurrent meteorological pattern.

The gotten results from this study have shown how Nino’s conditions, that were characterized February 2010, were predictable since October 2009; so, far in advance, we would be able to wait higher temperatures in comparison with the average ones and, with similar altitude, a greater number of rainy precipitations.

The research is integrated with the evaluation of the bio-climatical aspects and with the study of the influence of amperic variables on carrying out the physical activity. Using the climatic index NFI, we have demonstrated how the combined action of wind and humidity can contribute in decreasing the value of perceived temperature even of 6°C.

In conclusion, by applying the “S.F.E.R.A.” model and the natural evolution of the “Nino S.F.E.R.A.”, it’s possible to develop a “performance analysis” on some athletes participating to different competitions in alpine skiing during Vancouver’s Olympic Games. This analysis has underlined how the uncertainty level resulting from the meteorological aspects is among the most substantial one, this confirm that the athlete's performance are strongly influenced by environmental conditions.

**Movement variability and stability in aerobic gymnastics at different skill levels**

M. Bonanomi, D. Galante, L. Fusini, A. Malpedi, D. Schiavon, C. Strozzi

Sport performance during closed skills execution combines body movements into codified patterns. High levels of movement consistency are believed to be typical of skilled athletes: once a skilled performance has been achieved, the ability to optimally refine these characteristics will likely result in a consistent performance with low variability.

In this study, we analyzed the variability of body trajectories between expert and novice gymnasts executing a completion element. Eleven female gymnasts (6 novice, 5 expert) performed 10 repetitions of a complex jump (air turn to split), an element of aerobic gymnastics competition. On each gymnast, the 3D coordinates of 12 body landmarks were recorded by a motion analyzer, and a 3D reconstruction of the movement trajectories of center of mass (CoM) was performed. Five variables representing pre-jump height, jump height, pre-jump length, jump length and coupling time were determined.

To assess execution variability, the coefficient of variation (CV) was calculated across the 10 repetitions for each variable. To quantitatively evaluate dynamic stability, the Lyapunov exponents (LyE) were computed for ensemble time series of CoM displacements.

No significant differences between groups were observed in the CV (p>0.05). LyE values were comprised between 0.05 and 0.10. When comparing LyE of latero-medial displacements, a significant (p<0.001) higher level of stability was identified in the novice group.

Contrary to predictions, there was not a clear pattern of reduction in variability with increasing skill level as reported in a previous study. However, a high level of stability was identified, suggesting that the movement patterns were consistent in both groups.

**Strength performances in aerobic gymnastics**

A. Pusino, M. Bonanomi, D. Schiavon

Scuola Universitaria Interfacoltà in Scienze Motorie; SUISS, Università degli Studi di Torino, Italy

Aerobic Gymnastics is the ability to perform continuous complex and high intensity movement patterns to music, which originate from traditional aerobic exercises, the routine most demonstrate continuous movement, flexibility, strength, with perfectly executed all the movements including the difficulty elements. The definition of the performance model of a discipline that has been emerging recently but that, up to now, has not been examined deeply by the scientific world, is a fundamental step.

For our purpose, sixteen interregional aerobicists athletes, aged between 8 and 18 years, have been examined. The aim of the study was to valuing the strength performances of this group and to compare them to the performances of similar sports. In order to examine this comparison, we employed a set of tests calculating the different features of explosive muscular strength for the upper and lower limbs. The tests were: Squat Jump (SJ), Counter Movement Jump (CMJ), Counter Movement Jump with Free Arms (CMJFA), Stiffness Test, Multiple Jumps 15'' and Bench Press. The average height in SJ test was 23.8±0.6 cm, in CMJ 24.9±1.7 cm, in CMJFA 39.0±1.1 cm, in Stiffness Test 143.7±10.5 Nm, in Multiple Jumps 15' 22.0±2.9 cm, whereas for the upper limbs the mean value was 170.5±15.3 W in Bench Press test.

The results of the lower limb explosive force and reactivity are a little higher than the results obtained by gymnastics athletes of the same age and the same qualifying level; nevertheless, these data are lower in comparison with the data from other sports activities.

Although literature does not show any comparison for the Bench Press test with the same age athletes, the parameters cannot be considered very high. From that, we can easily understand that the explosive force in general is not sufficiently developed for reaching higher technical objectives. Even though the results are not satisfactory, the level is in line with national athletes.

**Development of a sport-specific test battery to assess climbing performance**
