Abstract

In this paper, a cell based smoothed finite element method with discrete shear gap technique is employed to study the static bending, free vibration, mechanical and thermal buckling behaviour of functionally graded material (FGM) plates. The plate kinematics is based on the first order shear deformation theory and the shear locking is suppressed by a discrete shear gap method. The shear correction factors are evaluated by employing the energy equivalence principle. The material property is assumed to be temperature dependent and graded only in the thickness direction. The effective properties are computed by using the Mori-Tanaka homogenization method. The accuracy of the present formulation is validated against available solutions. A systematic parametric study is carried out to examine the influence the gradient index, the plate aspect ratio, skewness of the plate and the boundary conditions on the global response of the FGM plates. The effect of a centrally located circular cutout on the global response is also studied.

Keywords: functionally graded material, cell based smoothed finite element method, discrete shear gap, viscoelastic, boundary conditions, gradient index, circular cutout

1. Introduction

With the rapid advancement of engineering, there is an increasing demand for new materials which suits the harsh working environment without loosing its mechanical, thermal or electrical properties. Engineered materials such as the composite materials are used due to their excellent strength-to and stiffness-to-weight ratios and their possibility of tailoring the properties in optimizing their structural response. But due to the abrupt change in material properties from matrix to fibre and between the layers, these materials suffer from pre-mature failure or by the decay in the stiffness characteristics because of delaminations and chemically unstable matrix and lamina adhesives. On the contrary, another class of materials, called, the Functionally Graded Materials (FGM) are made up of mixture of ceramics and metals and are characterized by smooth and continuous transition in properties from one surface to another [15]. As a result, FGMs are preferred over the laminated composites for structural integrity. The FGMs combine the best properties of the ceramics and the metals and this has attracted the researchers to study the characteristics of such structures.

Background. The tunable thermo-mechanical property of the FGM has attracted researchers to study the static and the dynamic behaviour of structures made of FGM under mechanical \([43, 44, 32, 38]\) and thermal loading \([21, 29, 8, 13, 45, 46]\). Praveen et al., \([29]\) and Reddy et al., \([34]\) studied the thermo-elastic response of ceramic-metal plates using first order shear deformation theory coupled with the 3D heat conduction equation. Their study concluded that the structures made up of FGM with ceramic rich side exposed to elevated temperatures are susceptible to buckling due to the through thickness temperature variation. The buckling of skewed FGM plates under mechanical and thermal loads were studied in \([8, 9]\) employing the first order shear deformation theory and by using the shear flexible quadrilateral element. Efforts has also been made to study the mechanical behaviour of FGM plates with geometrical imperfection \([36]\). Saji et al., \([35]\) has studied thermal buckling of FGM plates with material properties dependent on both the composition and temperature. They found that Critical buckling temperatures are decreased when material properties are considered to be a function of temperature as compared to the results obtained where material properties are assumed to be independent of temperature. In ref.\([8]\) Ganapati et. al. has studied the buckling of FGM skewed plate under thermal loading. Efforts has also been made to study the mechanical behaviour of FGM plates with geometrical imperfection \([36]\).

Existing approaches in the literature to study plate and shell structures made up of FGMs uses finite element method (FEM) based on Lagrange basis functions \([23, 30]\) and recently Valizadeh et al., \([40]\) used non-uniform rational B-splines based FEM to study the static and dynamic characteristics of FGM plates in thermal environment. Another set of methods have emerged to address the shear locking in the FEM. By incorporating the strain smoothing technique into the finite element method (FEM), Liu et al., \([20]\) have formulated a series of smoothed finite element methods (SFEM), named as cell-based SFEM (CS-FEM) \([24, 3]\), node-based SFEM \([19]\), edge-based SFEM \([18]\), face-based SFEM \([23]\) and \(\alpha\)-FEM \([17]\). And recently, edge based imbricate finite element method (EI-FEM) was proposed in \([5]\) that shares common features with the ES-FEM. As the SFEM can be recast within a Hellinger-Reissner variational principle, suitable choices of the assumed strain/gradient space provides stable solutions. Depending on the number and geometry of the subcells used, a spectrum of methods exhibiting a spectrum of properties is obtained. Interested are referred to the literature \([? 24]\) and references therein. Nguyen-Xuan et al., \([26]\) employed CS-FEM for Mindlin-Reissner plates. The curvature at each point is obtained by a non-local approximation via a smoothing function. From the numerical studies presented, it was concluded that the CS-FEM technique is robust, computationally inexpensive, free of locking and importantly insensitive to mesh distortions. The SFEM was extended to various problems such as shells \([28]\), heat transfer \([42]\), fracture mechanics \([25]\) and structural acoustics \([11]\) among others. In \([4]\), CS-FEM has been combined with the extended FEM to address problems involving discontinuities. The above list is no way comprehensive and interested readers are referred to the literature and references therein and a recent review paper by Jha and Kant \([14]\) on FGM plates.

Approach. In this paper, we study the static and the dynamic characteristics of FGM plates are studied by using a cell-based smoothed finite element method with discrete shear gap technique. Three-noded triangular element is employed in this study. The effect of different parameters viz., the material gradient index, the plate aspect ratio, the plate slenderness ratio and the boundary condition on the global response of FGM plates are numerically studied. The effect of centrally located circular cutout is also studied.

Outline. The paper is organized as follows, the next section will give an introduction to FGM and a brief overview of Reissner-Mindlin plate theory. Section\([3]\) presents an overview of the cell-based smoothed finite element method with discrete shear gap technique. The efficiency of the present formulation, numerical results and parametric studies are presented in Section\([4]\) followed by concluding remarks in the last section.
2. Theoretical Background

2.1. Reissner-Mindlin plate theory

The Reissner-Mindlin plate theory, also known as the first order shear deformation theory (FSDT) takes into account the shear deformation through the thickness. Using the Mindlin formulation, the displacements \( u, v, w \) at a point \((x, y, z)\) in the plate (see Figure 1) from the medium surface are expressed as functions of the mid-plane displacements \( u_o, v_o, w_o \) and independent rotations \( \theta_x, \theta_y \) of the normal in \(yz\) and \(xz\) planes, respectively, as:

\[
\begin{align*}
    u(x, y, z, t) &= u_o(x, y, t) + z\theta_x(x, y, t) \\
    v(x, y, z, t) &= v_o(x, y, t) + z\theta_y(x, y, t) \\
    w(x, y, z, t) &= w_o(x, y, t)
\end{align*}
\]  

(1)

where \( t \) is the time. The strains in terms of mid-plane deformation can be written as:

\[
\varepsilon = \begin{bmatrix} \varepsilon_p \\ 0 \\ \varepsilon_s \end{bmatrix} + \begin{bmatrix} z\varepsilon_b \end{bmatrix}
\]

(2)

where the subscript ‘comma’ represents the partial derivative with respect to the spatial coordinate succeeding it.

The midplane strains \( \varepsilon_p \), the bending strain \( \varepsilon_b \) and the shear strain \( \varepsilon_s \) in Equation (2) are written as:

\[
\varepsilon_p = \begin{bmatrix} u_{o,x} \\ v_{o,y} \\ u_{o,y} + v_{o,x} \end{bmatrix}, \quad \varepsilon_b = \begin{bmatrix} \theta_{x,x} \\ \theta_{y,y} \\ \theta_{x,y} + \theta_{y,x} \end{bmatrix}, \quad \varepsilon_s = \begin{bmatrix} \theta_x + w_{o,x} \\ \theta_y + w_{o,y} \end{bmatrix}
\]

(3)

where \( x, y \) are the coordinates in the plate and \( w_{o,x}, w_{o,y} \) are the thickness variations of the plate.

Figure 1: (a) coordinate system of a rectangular FGM plate, (b) Coordinate system of a skew plate

The membrane stress resultants \( N \) and the bending stress resultants \( M \) can be related to the membrane strains, \( \varepsilon_p \) and bending strains \( \varepsilon_b \) through the following constitutive relations:
\[ \mathbf{N} = \begin{pmatrix} N_{xx} \\ N_{yy} \\ N_{xy} \end{pmatrix} = A\mathbf{e}_p + B\mathbf{e}_b - \mathbf{N}^{th} \]

\[ \mathbf{M} = \begin{pmatrix} M_{xx} \\ M_{yy} \\ M_{xy} \end{pmatrix} = B\mathbf{e}_p + D_b\mathbf{e}_b - \mathbf{M}^{th} \quad (4) \]

where the matrices \( A = A_{ij}, B = B_{ij} \) and \( D_b = D_{ij}; (i, j = 1, 2, 6) \) are the extensional, bending-extensional coupling and bending stiffness coefficients and are defined as:

\[ \{A_{ij}, B_{ij}, D_{ij}\} = \int_{-h/2}^{h/2} \mathcal{Q}_{ij} \{1, z, z^2\} \, dz \quad (5) \]

Similarly, the transverse shear force \( Q = \{Q_{xz}, Q_{yz}\} \) is related to the transverse shear strains \( \varepsilon_s \) through the following equation:

\[ Q_{ij} = E_{ij}\varepsilon_s \quad (6) \]

where \( E_{ij} = \int_{-h/2}^{h/2} \mathcal{Q} u_i u_j \, dz; (i, j = 4, 5) \) is the transverse shear stiffness coefficient, \( u_i, u_j \) is the transverse shear coefficient for non-uniform shear strain distribution through the plate thickness. The stiffness coefficients \( \mathcal{Q}_{ij} \) are defined as:

\[ \mathcal{Q}_{11} = \mathcal{Q}_{22} = \frac{E(z)}{1 - \nu^2}; \quad \mathcal{Q}_{12} = \frac{\nu E(z)}{1 - \nu^2}; \quad \mathcal{Q}_{16} = \mathcal{Q}_{26} = 0 \]

\[ \mathcal{Q}_{44} = \mathcal{Q}_{55} = \mathcal{Q}_{66} = \frac{E(z)}{2(1 + \nu)} \quad (7) \]

where the modulus of elasticity \( E(z) \) and Poisson’s ratio \( \nu \) are given by Equation (21). The thermal stress resultant \( \mathbf{N}^{th} \) and the moment resultant \( \mathbf{M}^{th} \) are:

\[ \mathbf{N}^{th} = \begin{pmatrix} N_{xx}^{th} \\ N_{yy}^{th} \\ N_{xy}^{th} \end{pmatrix} = \int_{-h/2}^{h/2} \mathcal{Q}_{ij} \alpha(z, T) \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix} \Delta T(z) \, dz \]

\[ \mathbf{M}^{th} = \begin{pmatrix} M_{xx}^{th} \\ M_{yy}^{th} \\ M_{xy}^{th} \end{pmatrix} = \int_{-h/2}^{h/2} \mathcal{Q}_{ij} \alpha(z, T) \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix} \Delta T(z) \, dz \quad (8) \]

where the thermal coefficient of expansion \( \alpha(z, T) \) is given by Equation (22) and \( \Delta T(z) = T(z) - T_o \) is the temperature rise from the reference temperature and \( T_o \) is the temperature at which there are no thermal strains. The strain energy function \( U \) is given by:

\[ U(\delta) = \frac{1}{2} \int_{\Omega} \left\{ \varepsilon_p^T A \varepsilon_p + \varepsilon_p^T B e_b + \varepsilon_b^T B e_p + \varepsilon_b^T D e_b + \varepsilon_s^T E e_s - \varepsilon_p^T N^{th} - \varepsilon_b^T M^{th} \right\} \, d\Omega \quad (9) \]
where \( \delta = \{ u, v, w, \theta_x, \theta_y \} \) is the vector of the degree of freedom associated to the displacement field in a finite element discretization. Following the procedure given in [31], the strain energy function \( U \) given in Equation (9) can be rewritten as:

\[
U(\delta) = \frac{1}{2} \delta^T K \delta
\]  

(10)

where \( K \) is the linear stiffness matrix. The kinetic energy of the plate is given by:

\[
T(\delta) = \frac{1}{2} \int_{\Omega} \left\{ p\left( \dot{u}^2_o + \dot{v}^2_o + \dot{w}^2_o \right) + I(\dot{\theta}_x^2 + \dot{\theta}_y^2) \right\} \, d\Omega
\]  

(11)

where \( p = \int_{-h/2}^{h/2} \rho(z) \, dz \), \( I = \int_{-h/2}^{h/2} z^2 \rho(z) \, dz \) and \( \rho(z) \) is the mass density that varies through the thickness of the plate. When the plate is subjected to a temperature field, this in turn results in in-plane stress resultants, \( N^{th} \). The external work due to the in-plane stress resultants developed in the plate under a thermal load is given by:

\[
V(\delta) = \int_{\Omega} \left\{ \frac{1}{2} \left[ N_{xx}^{th} w_x^2 + N_{yy}^{th} w_y^2 + 2N_{xy}^{th} w_x w_y \right] + \frac{h^2}{24} \left[ N_{xx}^{th} (\theta_x^2 + \theta_y^2) + N_{yy}^{th} (\theta_x^2 + \theta_y^2) + 2N_{xy}^{th} (\theta_{x,y} \theta_{x,y} + \theta_{x,y} \theta_{x,y}) \right] \right\} \, d\Omega
\]  

(12)

Substituting Equation (9) - (12) in Lagrange’s equation of motion, one obtains the following finite element equations:

**Static bending:**

\[
(K + \square) \delta = F
\]  

(13)

**Free vibration:**

\[
M \ddot{\delta} + (K + K_G) \delta = 0
\]  

(14)

**Buckling analysis:**

**Mechanical Buckling.**

\[
(K + \lambda K_G) \delta = 0
\]  

(15)

**Thermal Buckling.**

\[
(K + \Delta T K_G) \delta = 0
\]  

(16)

where \( \delta \) is the vector of degree of freedom associated to the displacement field in a finite element discretization, \( \Delta T(= T_c - T_m) \) is the critical temperature difference, \( \lambda \) is the critical buckling load and \( K, K_G \) are the linear stiffness and geometric stiffness matrices, respectively. The critical temperature difference is computed using a standard eigenvalue algorithm.

### 2.2. Functionally graded material

A rectangular plate made of a mixture of ceramic and metal is considered with the coordinates \( x, y \) along the in-plane directions and \( z \) along the thickness direction (see Figure (1)). The material on the top surface \( (z = h/2) \) of the plate is ceramic rich and is graded to metal at the bottom surface of the plate \( (z = -h/2) \) by a power law distribution. The effective properties of the FGM plate can be computed by using the rule of mixtures or by employing the Mori-Tanaka homogenization scheme. Let \( V_i (i = c, m) \) be the volume fraction of the phase
material. The subscripts \( c \) and \( m \) refer to ceramic and metal phases, respectively. The volume fraction of ceramic and metal phases are related by \( V_c + V_m = 1 \) and \( V_c \) is expressed as:

\[
V_c(z) = \left( \frac{2z + h}{2h} \right)^n
\]  

(17)

where \( n \) is the volume fraction exponent \((n \geq 0)\), also known as the gradient index. The variation of the composition of ceramic and metal is linear for \( n = 1 \), the value of \( n = 0 \) represents a fully ceramic plate and any other value of \( n \) yields a composite material with a smooth transition from ceramic to metal.

**Rule of mixtures**

Based on the rule of mixtures, the effective property of a FGM is computed using the following expression:

\[
P = P_c V_c + P_m V_m
\]  

(18)

**Mori-Tanaka homogenization method**

Based on the Mori-Tanaka homogenization method, the effective Young’s modulus and Poisson’s ratio are computed from the effective bulk modulus \( K \) and the effective shear modulus \( G \) as [39]:

\[
\frac{K_{\text{eff}} - K_m}{K_c - K_m} = \frac{V_c}{1 + V_m \frac{3(K_c - K_m)}{5K_m + 4G_m}} \quad \frac{G_{\text{eff}} - G_m}{G_c - G_m} = \frac{V_c}{1 + V_m \frac{(G_c - G_m)}{(G_m + f_1)}}
\]  

(19)

where

\[
f_1 = \frac{G_m(9K_m + 8G_m)}{6(K_m + 2G_m)}
\]  

(20)

The effective Young’s modulus \( E_{\text{eff}} \) and Poisson’s ratio \( \nu_{\text{eff}} \) can be computed from the following relations:

\[
E_{\text{eff}} = \frac{3K_{\text{eff}}G_{\text{eff}}}{3K_{\text{eff}} + G_{\text{eff}}} \quad \nu_{\text{eff}} = \frac{3K_{\text{eff}} - 2G_{\text{eff}}}{2(3K_{\text{eff}} + G_{\text{eff}})}
\]  

(21)

The effective mass density \( \rho \) is computed using the rule of mixtures. The effective heat conductivity \( \kappa_{\text{eff}} \) and the coefficient of thermal expansion \( \alpha_{\text{eff}} \) is given by:

\[
\frac{\kappa_{\text{eff}} - \kappa_m}{\kappa_c - \kappa_m} = \frac{V_c}{1 + V_m \frac{(\kappa_c - \kappa_m)}{3\kappa_m}}
\]

\[
\frac{\alpha_{\text{eff}} - \alpha_m}{\alpha_c - \alpha_m} = \frac{\left( \frac{1}{K} - \frac{1}{K_m} \right)}{\left( \frac{1}{K} - \frac{1}{K_m} \right)}
\]  

(22)

**Temperature dependent material property.** The material properties that are temperature dependent are written as [39]:

\[
P = P_o(P_{-1}T^{-1} + 1 + P_1T + P_2T^2 + P_3T^3)
\]  

(23)

where \( P_o, P_{-1}, P_1, P_2 \) and \( P_3 \) are the coefficients of temperature \( T \) and are unique to each constituent material phase.

**Temperature distribution through the thickness**

The temperature variation is assumed to occur in the thickness direction only and the temperature field is considered to be constant in the \( xy \)-plane. In such a case, the temperature distribution along the thickness can be
obtained by solving a steady state heat transfer problem:

$$-\frac{d}{dz} \left[ \kappa(z) \frac{dT}{dz} \right] = 0, \quad T = T_c \text{ at } z = h/2; \quad T = T_m \text{ at } z = -h/2$$  \hspace{1cm} (24)

The solution of Equation (24) is obtained by means of a polynomial series \([41]\) as

$$T(z) = T_m + (T_c - T_m) \eta(z, h)$$  \hspace{1cm} (25)

where,

$$\eta(z, h) = \frac{1}{C} \left[ \frac{(2z + h)}{2h} - \frac{\kappa_{cm}}{(n + 1)\kappa_m} \left( \frac{2z + h}{2h} \right)^n \right] + \frac{\kappa_{cm}^2}{(2n + 1)\kappa_m^2} \left( \frac{2z + h}{2h} \right)^{2n} - \frac{\kappa_{cm}^3}{(3n + 1)\kappa_m^3} \left( \frac{2z + h}{2h} \right)^{3n} + \frac{\kappa_{cm}^4}{(4n + 1)\kappa_m^4} \left( \frac{2z + h}{2h} \right)^{4n} - \frac{\kappa_{cm}^5}{(5n + 1)\kappa_m^5} \left( \frac{2z + h}{2h} \right)^{5n} \right];$$  \hspace{1cm} (26)

$$C = 1 - \frac{\kappa_{cm}}{(n + 1)\kappa_m} + \frac{\kappa_{cm}^2}{(2n + 1)\kappa_m^2} - \frac{\kappa_{cm}^3}{(3n + 1)\kappa_m^3} + \frac{\kappa_{cm}^4}{(4n + 1)\kappa_m^4} - \frac{\kappa_{cm}^5}{(5n + 1)\kappa_m^5}$$  \hspace{1cm} (27)

3. Cell based smoothed finite element method with discrete shear gap technique

In this study, three-noded triangular element with five degrees of freedom (dofs) \(\delta = \{u, v, w, \theta_x, \theta_y\}\) is employed. The displacement is approximated by

$$\mathbf{u}^h = \sum_i N_i \delta_i$$  \hspace{1cm} (28)

where \(\delta_i\) are the nodal dofs and \(N_i\) are the standard finite element shape functions given by

$$N = \begin{bmatrix} 1 - \xi - \eta, & \eta, & \xi \end{bmatrix}$$  \hspace{1cm} (29)

In the CS-DSG3, each triangular element is divided into three subtriangles. The displacement vector at the center node is assumed to be the simple average of the three displacement vectors of the three field nodes. In each subtriangle, the stabilized DSG3 is used to compute the strains and also to avoid the transverse shear locking. Then the strain smoothing technique on the whole triangular element is used to smooth the strains on the three subtriangles.

Consider a typical triangular element \(\Omega_e\) as shown in Figure (2). This is first divided into three subtriangles \(\Delta_1, \Delta_2\) and \(\Delta_3\) such that \(\Omega_e = \bigcup_{i=1}^{3} \Delta_i\). The coordinates of the center point \(x_o = (x_o, y_o)\) is given by:

$$(x_o, y_o) = \frac{1}{3} (x_i, y_i)$$  \hspace{1cm} (30)
Figure 2: A triangular element is divided into three subtriangles. $\Delta_1$, $\Delta_2$ and $\Delta_3$ are the subtriangles created by connecting the central point $O$ with three field nodes.

The displacement vector of the center point is assumed to be a simple average of the nodal displacements as

$$\delta_{eO} = \frac{1}{3} \delta_{el}$$

(31)

The constant membrane strains, the bending strains and the shear strains for subtriangle $\Delta_1$ is given by:

$$\mathbf{\varepsilon}_p = \begin{bmatrix} \mathbf{p}_1^\Delta_1 & \mathbf{p}_2^\Delta_1 & \mathbf{p}_3^\Delta_1 \end{bmatrix} \begin{bmatrix} \delta_{eO} \\ \delta_{e1} \\ \delta_{e2} \end{bmatrix}$$

$$\mathbf{\varepsilon}_b = \begin{bmatrix} \mathbf{b}_1^\Delta_1 & \mathbf{b}_2^\Delta_1 & \mathbf{b}_3^\Delta_1 \end{bmatrix} \begin{bmatrix} \delta_{eO} \\ \delta_{e1} \\ \delta_{e2} \end{bmatrix}$$

$$\mathbf{\varepsilon}_s = \begin{bmatrix} \mathbf{s}_1^\Delta_1 & \mathbf{s}_2^\Delta_1 & \mathbf{s}_3^\Delta_1 \end{bmatrix} \begin{bmatrix} \delta_{eO} \\ \delta_{e1} \\ \delta_{e2} \end{bmatrix}$$

(32)

Upon substituting the expression for $\delta_{eO}$ in Equation (32), we obtain:
\[ \varepsilon_{p}^{\Delta_1} = \begin{bmatrix} \frac{1}{3} \mathbf{p}_1^{\Delta_1} + \mathbf{p}_2^{\Delta_1} + \frac{1}{3} \mathbf{p}_3^{\Delta_1} + \frac{1}{3} \mathbf{p}_1^{\Delta_1} \end{bmatrix} \begin{bmatrix} \delta_{e1} \\ \delta_{e2} \\ \delta_{e3} \end{bmatrix} = \mathbf{B}_{p}^{\Delta_1} \delta_{e} \]

\[ \varepsilon_{b}^{\Delta_1} = \begin{bmatrix} \frac{1}{3} \mathbf{b}_1^{\Delta_1} + \mathbf{b}_2^{\Delta_1} + \frac{1}{3} \mathbf{b}_3^{\Delta_1} + \frac{1}{3} \mathbf{b}_1^{\Delta_1} \end{bmatrix} \begin{bmatrix} \delta_{e1} \\ \delta_{e2} \\ \delta_{e3} \end{bmatrix} = \mathbf{B}_{b}^{\Delta_1} \delta_{e} \]

\[ \varepsilon_{s}^{\Delta_1} = \begin{bmatrix} \frac{1}{3} \mathbf{s}_1^{\Delta_1} + \mathbf{s}_2^{\Delta_1} + \frac{1}{3} \mathbf{s}_3^{\Delta_1} + \frac{1}{3} \mathbf{s}_1^{\Delta_1} \end{bmatrix} \begin{bmatrix} \delta_{e1} \\ \delta_{e2} \\ \delta_{e3} \end{bmatrix} = \mathbf{B}_{s}^{\Delta_1} \delta_{e} \]  

(33)

where \( \mathbf{p}_i, (i = 1, 2, 3) \), \( \mathbf{b}_i, (i = 1, 2, 3) \) and \( \mathbf{s}_i, (i = 1, 2, 3) \) are given by:

\[ \mathbf{B}_{p} = \frac{1}{2A_e} \begin{bmatrix} b - c & 0 & 0 & 0 & 0 & c & 0 & 0 & 0 & 0 & -b & 0 & 0 & 0 & 0 \\ 0 & d - a & 0 & 0 & 0 & 0 & -d & 0 & 0 & 0 & a & 0 & 0 & 0 & 0 \\ d - a & b - c & 0 & 0 & 0 & -d & c & 0 & 0 & 0 & a & -b & 0 & 0 & 0 \end{bmatrix} \]

\[ \mathbf{B}_{b} = \frac{1}{2A_e} \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & b - c & 0 & 0 & 0 & c & 0 & 0 & 0 & 0 & -b & 0 \\ 0 & 0 & 0 & 0 & d - a & 0 & 0 & 0 & 0 & -d & 0 & 0 & 0 & a & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & d - a & b - c & 0 & 0 & 0 & -d & c & 0 & 0 & 0 & a & -b \end{bmatrix} \]

\[ \mathbf{B}_{s} = \frac{1}{2A_e} \begin{bmatrix} 0 & 0 & b - c & A_e & 0 & 0 & c & ac/2 & bc/2 & 0 & 0 & -b & -bd/2 & -bc/2 \\ 0 & 0 & d - a & 0 & A_e & 0 & 0 & -d & -ad/2 & -bd/2 & 0 & 0 & a & ad/2 & ac/2 \end{bmatrix} \]  

(34)

where \( a = x_2 - x_1; b = y_2 - y_1; c = y_3 - y_1 \) and \( d = x_3 - x_1 \) (see Figure (3)), \( A_e \) is the area of the triangular element and \( \mathbf{B}_{s} \) is altered shear strains \( [3] \). The strain-displacement matrix for the other two triangles can be obtained by cyclic permutation.

Now applying the cell-based strain smoothing \( [3] \), the constant membrane strains, the bending strains and the shear strains are respectively employed to create a smoothed membrane strain \( \varepsilon_{p}^{s} \), smoothed bending strain \( \varepsilon_{b}^{s} \) and smoothed shear strain \( \varepsilon_{s}^{s} \) on the triangular element \( \Omega_{e} \) as:
\[ \overline{\varepsilon}_p = \int_{\Omega_c} \varepsilon_p \Phi_e(x) \, d\Omega = \sum_{i=1}^{3} \varepsilon^\Delta_i \int_{\Delta_i} \Phi_e(x) \, d\Omega \]

\[ \overline{\varepsilon}_b = \int_{\Omega_c} \varepsilon_b \Phi_e(x) \, d\Omega = \sum_{i=1}^{3} \varepsilon^\Delta_i \int_{\Delta_i} \Phi_e(x) \, d\Omega \]

\[ \overline{\varepsilon}_s = \int_{\Omega_c} \varepsilon_s \Phi_e(x) \, d\Omega = \sum_{i=1}^{3} \varepsilon^\Delta_i \int_{\Delta_i} \Phi_e(x) \, d\Omega \]

(36)

where \( \Phi_e(x) \) is a given smoothing function that satisfies. In this study, following constant smoothing function is used:

\[ \Phi(x) = \begin{cases} 1/A_c & x \in \Omega_c \\ 0 & x \notin \Omega_c \end{cases} \quad (37) \]

where \( A_c \) is the area of the triangular element, the smoothed membrane strain, the smoothed bending strain and the smoothed shear strain is then given by

\[ \{ \overline{\varepsilon}_p, \overline{\varepsilon}_b, \overline{\varepsilon}_s \} = \frac{\sum_{i=1}^{3} A_{\Delta_i} \{ \varepsilon^\Delta_i, \varepsilon^\Delta_i, \varepsilon^\Delta_i \}}{A_e} \quad (38) \]

The smoothed elemental stiffness matrix is given by

\[ K = \int_{\Omega_c} \left[ \mathbf{B}_p \mathbf{A}^T \mathbf{B}_p + \mathbf{B}_p \mathbf{B}^T \mathbf{B}_b + \mathbf{B}_b \mathbf{B}^T \mathbf{B}_p + \mathbf{B}_b \mathbf{D} \mathbf{B}^T \mathbf{b} + \mathbf{B}_s \mathbf{E} \mathbf{B}^T \mathbf{s} \right] \, d\Omega \]

\[ = \left[ \mathbf{B}_p \mathbf{A}^T \mathbf{B}_p + \mathbf{B}_p \mathbf{B}^T \mathbf{B}_b + \mathbf{B}_b \mathbf{B}^T \mathbf{B}_p + \mathbf{B}_b \mathbf{D} \mathbf{B}^T \mathbf{b} + \mathbf{B}_s \mathbf{E} \mathbf{B}^T \mathbf{s} \right] A_e \quad (39) \]
where $\mathbf{B}_p$, $\mathbf{B}_b$, and $\mathbf{B}_s$ are the smoothed strain-displacement matrix.

4. Numerical examples

In this section, we present the static bending response, the linear free vibration and buckling analysis of FGM plates using cell based smoothed finite element method with discrete shear gap technique. The effect of various parameters, viz., material gradient index $n$, skewness of the plate $\psi$, the plate aspect ratio $a/b$, the plate thickness $a/h$ and boundary conditions on the global response is numerically studied. The top surface of the plate is ceramic rich and the bottom surface of the plate is metal rich. Here, the modified shear correction factor obtained based on energy equivalence principle as outlined in [37] is used. The boundary conditions for simply supported and clamped cases are:

> **Simply supported boundary condition:**

$$u_o = w_o = \theta_y = 0 \quad \text{on} \quad x = 0, a; \quad v_o = w_o = \theta_x = 0 \quad \text{on} \quad y = 0, b \quad (40)$$

> **Clamped boundary condition:**

$$u_o = w_o = \theta_y = v_o = \theta_x = 0 \quad \text{on} \quad x = 0, a \quad \& \quad y = 0, b \quad (41)$$

**Skew boundary transformation.** For skew plates, the edges of the boundary elements may not be parallel to the global axes $(x, y, z)$. In order to specify the boundary conditions on skew edges, it is necessary to use the edge displacements $(u'_o, v'_o, w'_o)$ etc, in a local coordinate system $(x', y', z')$ (see Figure (1)). The element matrices corresponding to the skew edges are transformed from global axes to local axes on which the boundary conditions can be conveniently specified. The relation between the global and the local degrees of freedom of a particular node is obtained by:

$$\delta = L_g \delta' \quad (42)$$

where $\delta$ and $\delta'$ are the generalized displacement vector in the global and the local coordinate system, respectively.

The nodal transformation matrix for a node $I$ on the skew boundary is given by:

$$L_g = \begin{bmatrix}
\cos \psi & \sin \psi & 0 & 0 & 0 \\
-\sin \psi & \cos \psi & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & \cos \psi & \sin \psi \\
0 & 0 & 0 & -\sin \psi & \cos \psi 
\end{bmatrix} \quad (43)$$

where $\psi$ defines the skewness of the plate.

4.1. Static Bending

Let us consider a Al/ZrO$_2$ FGM square plate with length-to-thickness $a/h = 5$, subjected to a uniform load with fully simply supported (SSSS) and fully clamped (CCCC) boundary conditions. The Young’s modulus for ZrO$_2$ is $E_c = 151$ GPa and for aluminum is $E_m = 70$ GPa. Poisson’s ratio is chosen as constant, $\nu = 0.3$. Table [1] compares the results from the present formulation with other approaches available in the literature [10, 16, 27, 40] and a very good agreement can be observed. Next, we illustrate the performance of the present formulation for thin plate problems. A simply supported square plate subjected to uniform load is considered, while the length-to-thickness $(a/h)$ varies from $5$ to $10^4$. Two individual approaches are employed: discrete shear gap method referred to as DSG3 and the other referred as cell-based smoothed finite element method with discrete shear gap technique (CSDSG3). The plate is modeled with 1800 3 noded triangular elements. The normalized center deflection $\bar{W}_c = 100w_c\frac{E_c h^3}{12(1-\nu^2)pa^4}$ is shown in Figure (4). It is observed that the DSG3 results are subjected to shear locking when the plate becomes thin $(a/h > 100)$. However, the present formulation, CSDSG3 is less sensitive to shear locking.
Table 1: The normalized center deflection \( w_c = 100w_c \frac{E_h^3}{12(1-\nu^2)p_a} \) for a simply supported Al/ZrO\(_2\)-1 FGM square plate with \( a/h = 5 \), subjected to a uniformly distributed load \( p \).

4.2. Free flexural vibrations

In this section, the free flexural vibration characteristics of FGM plates with and without centrally located cutout in thermal environment is studied numerically. Figure (5) shows the geometry of the plate with a centrally located circular cutout. In all cases, we present the non-dimensionalized free flexural frequency defined as, unless otherwise stated:

\[ \bar{\omega} = \omega a^2 \sqrt{\frac{\rho_c h}{D_c}} \]  

where \( \omega \) is the natural frequency, \( \rho_c, D_c = \frac{E_c h^3}{12(1-\nu^2)} \) are the mass density and the flexural rigidity of the ceramic phase. The FGM plate considered here is made up of silicon nitride (Si$_3$N$_4$) and stainless steel (SUS304). The material is considered to be temperature dependent and the temperature coefficients corresponding to Si$_3$N$_4$/SUS304 are listed in Table 2 [33, 39]. The mass density (\( \rho \)) and the thermal conductivity (\( \kappa \)) are \( \rho_c = 2370 \text{ kg/m}^3, \kappa_c = 9.19 \text{ W/mK for Si}_3\text{N}_4 \) and \( \rho_m = 8166 \text{ kg/m}^3, \kappa_m = 12.04 \text{ W/mK for SUS304} \). Poisson’s ratio \( \nu \) is assumed to be constant and taken as 0.28 for the current study [39]. Before proceeding with a detailed study on the effect of gradient index on the natural frequencies, the formulation developed herein is validated against available analytical/numerical solutions pertaining to the linear frequencies of a FGM plate in thermal environment and a FGM plate with a centrally located circular cutout. The computed frequencies: (a) for a square simply supported FGM plate in thermal environment with \( a/h = 10 \) is given in Table 3 and (b) the mesh convergence and comparison of linear frequencies for a square plate with circular cutout is given in Tables 4 - 5. It can be seen that the numerical results from the present formulation are found to be in very good agreement with the existing solutions. For the uniform temperature case, the material properties are evaluated at \( T_c = T_m = 300 \text{K} \). The temperature is assumed vary only in the thickness direction and determined by Equation (25). The temperature for the ceramic surface is varied, whilst maintaining a constant value on the metallic surface is maintained (\( T_m = 300 \text{K} \)) to subject a thermal gradient. The geometric stiffness matrix is computed from the in-plane stress resultants due to the applied thermal gradient. The geometric stiffness matrix is then added to the stiffness matrix and the eigenvalue problem is solved. The effect of the material gradient index is also shown in Tables 3 & 5 and the influence of a centrally located cutout is shown in Tables 4 - 5. The combined effect of increasing the temperature and the gradient index is to lower the fundamental frequency, this is due to the increased metallic volume fraction. Figure (6) shows the influence of the cutout size on the frequency for a plate in thermal environment (\( \Delta T = 100 \text{K} \)). The frequency increases...

with increasing cutout size. This can be attributed to the decrease in stiffness degradation due to the presence of the hole. Also, it can be seen that with increasing gradient index, the frequency decreases. In this case, the decrease in the frequency is due to the increase in the metallic volume fraction. It is observed that the combined effect of increasing the gradient index and the cutout size is to lower the fundamental frequency. Increasing the thermal gradient further decreases the fundamental frequency.

15
Mechanical Buckling

The FGM plate considered here consists of Aluminum (Al) and Zirconium dioxide (ZrO$_2$). The material is considered to be temperature independent. The Young’s modulus ($E$) for ZrO$_2$ is $E_c = 151$ GPa and for Al is $E_m = 70$ GPa. For mechanical buckling, we consider both uni- and bi-axial mechanical loads on the FGM plates. In all cases, we present the critical buckling parameters as, unless otherwise specified:

$$\lambda_{cr} = \frac{N_{xxcr} b^2}{\pi^2 D_c}$$
$$\lambda_{crb} = \frac{N_{yycrb} b^2}{\pi^2 D_c}$$

where $\lambda_{cr}$ and $\lambda_{crb}$ are the critical buckling parameters for uni- and bi-axial load, respectively, $D_c = E_c h^3/(12(1 - \nu^2))$. The critical buckling loads evaluated by varying the skew angle of the plate, volume fraction index and considering mechanical loads such as uni- and biaxial compressive loads are shown in Tables 6 for $a/h = 100$. The efficacy of the present formulation is demonstrated by comparing our results with those in [9]. It can be seen that increasing the gradient index decreases the critical buckling load. A very good agreement in the results can be observed. It is also observed that the decrease in the critical value is significant for the material gradient index $n \leq 2$ and that further increase in $n$ yields less reduction in the critical value, irrespective of the skew angle. The effect of the plate aspect ratio and the gradient index on the critical buckling load is shown in Figure (7) for a simply supported FGM plate under uni-axial mechanical load. It is observed that the combined effect of increasing the gradient index and the plate aspect ratio is to lower the critical buckling load. Table 7 presents the critical buckling parameter for a simply supported FGM with a centrally located circular cutout with $r/a = 0.2$. It can be seen that the present formulation yields comparable results. The effect of increasing the gradient index is to lower the critical buckling load. This is due to the stiffness degradation due to increase in the metallic volume fraction. Figure (8) shows the influence of a centrally located circular cutout and the gradient index on the critical buckling load under two different boundary conditions, viz., all edges simply supported and all edges clamped. In this case, the plate is subjected to a uni-axial compressive load. It can be seen that increasing the gradient index decreases the critical buckling load due to increasing metallic volume fraction, whilst, increasing the cutout radius decreases the critical buckling load in the case of simply supported boundary conditions. This can be attributed to the stiffness degradation due to the presence of a cutout and the simply supported boundary condition. In case of the clamped boundary condition, the critical buckling load first decreases with increasing cutout radius due to stiffness degradation. Upon further increase, the critical buckling load increases. This is because, the clamped boundary condition adds stiffness to the system which overcomes the stiffness reduction due to the presence of a cutout.

Thermal Buckling

In this section, the thermal buckling behaviour of simply supported functionally graded skew plate is studied. The top surface is ceramic rich and the bottom surface is metal rich. The FGM plate considered here consists of aluminum and alumina. The Young’s modulus, the thermal conductivity and the coefficient of thermal expansion for alumina is $E_c = 380$ GPa, $K_c = 10.4$ W/mK, $\alpha_c = 7.4 \times 10^{-6}$ 1/°C, and for aluminum, $E_m = 70$ GPa, $K_m = 204$ W/mK, $\alpha_m = 23 \times 10^{-6}$ 1/°C, respectively. Poisson’s ratio is chosen as constant, $\nu = 0.3$. The temperature rise of $T_m = 5$ °C in the metal-rich surface of the plate is assumed in the present study. In addition to nonlinear temperature distribution across the plate thickness, the linear case is also considered in the present analysis by truncating the higher order terms in Equation (26). The plate is of uniform thickness and simply supported on all four edges. Table 8 shows the convergence of the critical buckling temperature with mesh size for different gradient index, $n$. It can be seen that the results from the present formulation are in good very agreement with the available solution. The influence of the plate aspect ratio $a/b$ and the skew angle $\psi$ on the critical buckling temperature for

Figure 8: Variation of the critical buckling load $\lambda_{cru} = \frac{N_{cr u}}{\pi D_m}$ with cutout dimensions for a square FGM plate with $a/h=10$ subjected to uniaxial compressive loading for different gradient index $n$ and various boundary conditions.
a simply supported square FGM plates are shown in Figures (9) and (10). It is seen that increasing the plate aspect ratio decreases the critical buckling temperature for both linear and nonlinear temperature distribution through the thickness. The critical buckling temperature increases with increase in the skew angle. The influence of the gradient index $n$ is also shown in Figure (10). It is seen that with increasing gradient index, $n$, the critical buckling temperature decreases. This is due to the stiffness degradation due to increase in the metallic volume fraction. Figure (11) shows the influence of the cutout radius and the material gradient index on the critical buckling temperature. Both linear and nonlinear temperature distribution through the thickness is assumed. Again, it is seen that the combined effect of increasing the gradient index $n$ and the cutout radius $r/a$ is to lower the frequency. For gradient index $n = 0$, there is no difference between the linear and the nonlinear temperature distribution through the thickness as the material is homogeneous through the thickness. While, for $n > 0$, the material is heterogeneous through the thickness with different thermal property.

5. Conclusion

In this paper, we applied the cell-based smoothed finite element method with discrete shear gap technique to study the static and the dynamic response of functionally graded materials. The first order shear deformation theory was used to describe the plate kinematics. The efficiency and accuracy of the present approach is demonstrated with few numerical examples. This improved finite element technique shows insensitivity to shear locking and produce excellent results in static bending, free vibration and buckling of functionally graded plates.
