Tsallis and Kaniadakis Entropic Measures in Polytropic, Logarithmic and Exponential Functions

Amelia Carolina Sparavigna¹

¹Department of Applied Science and Technology, Politecnico di Torino, Torino, Italy

Abstract: Among nonextensive statistical approaches, those proposed by Constantino Tsallis and Giorgio Kaniadakis had been involved in the study of several physical phenomena. Here, we will discuss the case of the polytropic solutions of self-gravitating fluid spheres used in astrophysics as approximate stellar models. We will see how, in this problem, Tsallis and Kaniadakis entropic measures are related. After, following the same approach, we will find the links between generalized logarithms and exponential functions of the abovementioned entropic measures.

Keywords: Entropy, Generalized Entropies

1. Introduction

The nonextensive statistical mechanics is a research on foundations of statistical mechanics, which is based on the generalization of the well-known Boltzmann–Gibbs theory. This statistical mechanics, which is formulated with different approaches, enables the study of systems with long-range interactions, long-term memories or multi-fractal structures [1]. The Tsallis and Kaniadakis approaches are two of the nonextensive generalizations of statistical mechanics, which had been involved in the discussion of several phenomena [1,2]. Among the possible examples, here we consider one from astrophysics. It is related to polytropes, the polytropic solutions of the Lane–Emden equation. This is an equation which gives the pressure as a function of density [3]. These solutions are modelling self-gravitating fluid spheres that are called “polytropes” too, which are objects used as approximation to more realistic stellar models [4]. The solution of the Lane–Emden equation, a dimensionless form of Poisson's equation for the gravitational potential, depends on a parameter known as the polytropic index n . It is usually written as $P = K\rho^{(n+1)/n}$, where P is pressure, ρ is density and K a constant. If stellar structure is approximated with a polytrope having a given index, two scaling parameters are needed to express the structure in physical units [5]. The two parameters that we can use are a constant related to the entropy and the stellar mass. Since Boltzmann distribution yields unphysical results, a generalized

entropy, the Tsallis entropy, was used in [6] instead of Boltzmann entropy. The use of Kaniadakis entropy had been recently proposed too, in [7]. Here we will see that these two entropic measures are related in polytropic solutions, and that the result given in [7] can be easily obtained from [6]. After, following the same approach used for polytropes, we will see how the generalized logarithms and exponential functions, used in these two nonextensive methods, are linked. Of course, this procedure can be easily repeated for all the generalized functions, based on the abovementioned measures.

2. The entropies

Well-known is the entropy proposed by Claude Shannon in 1948 [8]. He defined the entropy H of a discrete random variable X , as the expected value of the information content: $H(X) = -\sum_i p_i \log_b p_i$

. The probability of i -event is p_i and b is the base of the used logarithm. However, several entropies exist which are generalizing Shannon entropy. Among them we have Tsallis and Kaniadakis entropies [9,10], which are defined, with a corresponding choice of measurement units equal to 1, as follow:

$$(1) \quad \text{Tsallis :} \\ T = T_q = \frac{1}{q-1} \left(1 - \sum_i p_i^q \right)$$

(2) Kaniadakis (κ - entropy) :

$$K_{\kappa} = -\sum_i \frac{p_i^{1+\kappa} - p_i^{1-\kappa}}{2\kappa}$$

In (1) and (2) we have the entropic indices q and κ . For its generalized additivity, the Kaniadakis entropy requires another function, defined as follow:

$$\mathfrak{J} = \sum_i (p_i^{1+\kappa} + p_i^{1-\kappa})/2. \text{ A detailed discussion of}$$

the generalized additivity of Tsallis and κ -entropy is given in [11].

Tsallis and Kaniadakis entropies are linked:

$$(3) \quad K_{\kappa} = \frac{T_{1+\kappa} + T_{1-\kappa}}{2},$$

Where:

$$T(q = 1 + \kappa) = -\frac{1}{\kappa} \sum_i p_i^{1+\kappa} + \frac{1}{\kappa}$$

$$T(q = 1 - \kappa) = \frac{1}{\kappa} \sum_i p_i^{1-\kappa} - \frac{1}{\kappa}$$

Eq.(3) is a simpler form of an expression given in [12,13]. However, besides this relation, because of the generalized additivity possessed by the Kaniadakis entropy, we need also another relation:

$$(4) \quad \mathfrak{J}_{\kappa} = \frac{\kappa}{2} \left(-T_{1+\kappa} + T_{1-\kappa} + \frac{2}{\kappa} \right)$$

$$(8) \quad C_q(f) = \frac{f - f^q}{q-1} = \frac{1}{2(q-1)} (f^{2-q} - f^q) - \frac{1}{2(q-1)} (f^{2-q} + f^q) + \frac{f}{q-1}$$

Of course, (7) and (8) are the same equation. Therefore, Kaniadakis measures are linked to Tsallis measure by:

$$(9) \quad t_q(f) = C_q(f) = \frac{(f - f^q)}{q-1} = k_{1-q} - \frac{g_{1-q}}{q-1} + \frac{f}{q-1}$$

Where:

$$T_q = \sum_f t_q, \quad K_{1-q} = \sum_f k_{1-q}, \quad \mathfrak{J}_{1-q} = \sum_f g_{1-q}, \quad 1 = \sum_f f$$

From [6], a relation exists between polytrope index and entropic Tsallis index:

$$(10) \quad n = \frac{3}{2} + \frac{1}{q-1}$$

As a special case, for $q \rightarrow 1$, we find the isothermal situation. To have Eq.6, as shown in [14], we need

In (3) and (4), we have Kaniadakis functions expressed by Tsallis entropy. As shown in [14], we can also write T expressed by means of Kaniadakis functions:

$$(5) \quad K_{\kappa} + \frac{1}{\kappa} \mathfrak{J}_{\kappa} = T_{1-\kappa} + \frac{1}{\kappa}$$

Let us have: $\kappa = 1 - q$. From (5) we have immediately the relation between Tsallis entropy and Kaniadakis entropic measures:

$$(6) \quad T_q = K_{1-q} + \frac{\mathfrak{J}_{1-q} - 1}{(1-q)}$$

3. With polytropes

The relation (6) between Tsallis and Kaniadakis entropies can be useful in several problems. Here we consider its use in polytropes. In the previous equations, we have p_i denoting the probability distribution. In Ref.6, it is used letter f for probability. From now on, we will use this notation. In [6], the measure from Tsallis entropy is:

$$(7) \quad C_q(f) = \frac{f(1 - f^{q-1})}{q-1}$$

We can write Eq.7 in the following manner:

$\kappa = 1 - q$ or $\kappa = q - 1$. Then, from (10), considering that we have for the Kaniadakis index $-1 < \kappa < 1$, we find:

$$(11) \quad n = \frac{3}{2} + \frac{1}{\kappa}$$

In fact, (11) is the relation that we find in [7]. Using

then the relation between Tsallis and Kaniadakis measures we can easily find results concerning several applications. Polytropes are an example of such possible approach.

4. Logarithms

Following the example of polytropes, we can investigate the relation between generalized logarithms. In the framework of Tsallis approach, the logarithm is defined as:

$$(12) \ln_q^T(f) = \frac{f^{1-q} - 1}{1-q}$$

$$(15) \ln_q^T(f) = \frac{1-f^{1-q}}{q-1} = \frac{1}{2(q-1)}(f^{q-1} - f^{1-q}) - \frac{1}{2(q-1)}(f^{q-1} + f^{1-q}) + \frac{1}{q-1}$$

$$= \ln_{1-q}^K(f) + \frac{f^{1-q} + f^{q-1}}{2(1-q)} + \frac{1}{q-1} = \ln_{1-q}^K(f) + \frac{1}{f} \frac{f^{2-q} + f^q}{2(1-q)} + \frac{1}{q-1}$$

Here we find again, in (15), the measures found in (8). Then, we can write, as we did in (9):

$$(16) \ln_q^T(f) = \ln_{1-q}^K(f) + \frac{1}{f} \frac{g_{1-q}}{(1-q)} - \frac{1}{1-q}$$

In (16), we have the relation between Tsallis and Kaniadakis generalized logarithms.

5. Exponentials

In the framework of Tsallis approach, the exponential is defined as:

$$(17) e_q^T(f) = [1 + (1-q)f]^{1/(1-q)}$$

We have that: $e_q^T(\ln_q^T(f)) = f$. So:

$$e_q^T(\ln_q^T(f)) = \left[1 + (1-q) \left(\ln_{1-q}^K(f) + \frac{1}{f} \frac{g_{1-q}}{(1-q)} - \frac{1}{1-q} \right) \right]^{1/(1-q)}$$

$$= \left[(1-q) \ln_{1-q}^K(f) + \frac{g_{1-q}}{f} \right]^{1/(1-q)} = f$$

Therefore, we have also the relation (considering $\kappa = 1 - q$):

$$(18) \kappa \ln_{\kappa}^K(f) = -\frac{g_{\kappa}}{f} + f^{\kappa}.$$

In (18) we have an expression of the generalized logarithm, containing the Kaniadakis measure g_{κ} , where $\mathfrak{S}_{\kappa} = \sum_f g_{\kappa}$. (18) is in agreement with (16).

Let us consider the exponential from Kaniadakis measure:

$$(19) e_{\kappa}^K(f) = \left[\sqrt{1 + \kappa^2 f^2} + \kappa f \right]^{1/\kappa}$$

In the Kaniadakis approach:

$$(13) \ln_{\kappa}^K(f) = \frac{f^{\kappa} - f^{-\kappa}}{2\kappa}$$

Let us write (13), with $\kappa = 1 - q$:

$$(14) \ln_{1-q}^K(f) = \frac{f^{1-q} - f^{q-1}}{2(1-q)}$$

As we did for polytropes:

We have also $e_{\kappa}^K(\ln_{\kappa}^K(f)) = f$, and then:

$$(20) \quad e_{\kappa}^K(\ln_{\kappa}^K(f)) = \left[\sqrt{1 + \kappa^2 \left(\frac{f^{\kappa} - f^{-\kappa}}{2\kappa} \right)^2} + \kappa \left(\frac{f^{\kappa} - f^{-\kappa}}{2\kappa} \right) \right]^{1/\kappa} = \left[\frac{1}{f} g_{\kappa} + \kappa \frac{1}{f} k_{\kappa} \right]^{1/\kappa} = f$$

Let us remember that we have defined: $K_{\kappa} = \sum_f k_{\kappa}$, $\mathfrak{K}_{\kappa} = \sum_f g_{\kappa}$.

However:

$$(21) \quad \left[\frac{1}{f} g_{\kappa} + \kappa \frac{1}{f} k_{\kappa} \right] = f^{\kappa} \rightarrow g_{\kappa} + \kappa k_{\kappa} = f^{\kappa+1}$$

Then, we can find the following relation between the Tsallis exponential and the Kaniadakis measures:

$$(22) \quad e_q^T(f) = e_q^T(e_{1-q}^K \ln_{1-q}^K(f)) = \left[1 + (1-q) \left(\frac{g_{1-q}}{f} + (1-q) \frac{k_{1-q}}{f} \right)^{1/(1-q)} \right]^{1/(1-q)}$$

This is a link between Tsallis exponential function and Kaniadakis measures. In fact:

$$e_q^T(f) = e_q^T(e_{1-q}^K \ln_{1-q}^K(f)) = \left[1 + (1-q) \left(f^{(1-q)} \right)^{1/(1-q)} \right]^{1/(1-q)}$$

In the previous discussion, following the same approach used for polytropes, we have seen that generalized logarithms and exponential functions, used by Tsallis and Kaniadakis entropic measures, are linked. Of course, the same approach can be used for all the generalized functions that we can obtain in the framework of the abovementioned measures.
