DOI. 10.1137/15M1014760

1. Introduction. The simulation of flows in underground formations is a complex and challenging task, involving multiple physical phenomena on different scales and intricate computational domains. Among the different models available in the literature, discrete fracture network (DFN) models aim at a simplified representation of the network of fractures in the underground, but still reflecting the fracture pattern of the peculiar geological site under investigation and its key hydrological and geometrical characteristics [1, 12, 15]. A DFN is a stochastically generated network of fracture-resembling planar polygons in a three-dimensional space. Size, orientation, density, and hydrological properties of the fractures, such as the hydraulic transmissivity, are determined using probability distributions based on probing data and laboratory tests on soil specimens. Due to the stochastic nature of the input data, uncertainty quantification methods are then used to describe the flow properties [18, 6, 16]. The quantity of interest is the hydraulic head in the whole system of fractures, given by the sum of the pressure head and elevation. This is ruled by the Darcy law on each fracture with additional constraints of continuity and flux conservation at fracture intersections, called traces. Uncertainty quantification strategies for DFN problems require the repeated computation of the hydraulic head on stochastically generated networks; therefore reliability and efficiency of numerical tools are of paramount importance in this context. The major source of complexity lies in the intricate nature of the domain, characterized by intersecting fractures possibly with extremely narrow angles, almost overlapping parallel traces [10], and, due to the multiscale nature of the problem, the simultaneous presence of very small and very large fractures intersecting each other. As a consequence, the generation of a

†Dipartimento di Scienze Matematiche, Politecnico di Torino, 10129 Torino, Italy (stefano.berrone@polito.it, andrea.borio@polito.it, stefano.scialo@polito.it).
conforming mesh suitable for the resolution of the problem with finite element–based
discretizations might be very hard or even impossible [16]. A variety of strategies is
available in the literature in order to overcome these difficulties, mainly suggesting
the use of mortar methods to relax the conformity constraint at fracture intersections
[21, 22], sometimes coupled with mixed [13] and domain decomposition methods [23];
these geometrical difficulties may be even more relevant for more complex flow models
such as multiphase flows. In other papers the conformity requirement is accomplished
through modification of the geometry of the DFN [16, 19]. In the approach developed
in [7, 8, 9] the DFN problem is seen as a PDE-constrained optimization problem, in
which a cost functional measuring the discontinuity and flux unbalance at fracture
intersections is minimized, constrained by the Darcy law on the fractures. In this
framework, no mesh conformity is required at fracture intersections, and the solution
is obtained through the resolution of small weakly dependent subproblems on the
fractures with an iterative solver. Any difficulty related to the generation of the mesh
is avoided, and the approach has a natural parallel implementation with good scala-
bility performances [10]. Further, no modification of the geometry of the network is
required, and this is particularly important for uncertainty quantification procedures,
in which a modification of the disposition of fracture would imply a modification of
the probabilistic law at the basis of the generation of the network.

In the present paper, residual-based “a posteriori” error estimates [25, 26, 14,
17, 27, 2] are derived for the optimization formulation of the DFN problem described
above, in view of a possible future use within an adaptive algorithm. In deriving the a
posteriori error estimates, particular attention is devoted to highlighting the effect of
discontinuities of the discrete solution and unbalance of fluxes at fracture intersections
that can cross the interior of mesh elements. Indeed, the error estimator proposed
herein contains several additional terms with respect to classical residual-based a pos-
teriori error estimates; some of these additional terms exploit known properties of
the exact solution. Moreover, part of the work is devoted to estimating the errors
generated by the nonconformity of triangles to fracture intersections and to tracking
the influence of this nonconformity on the effectivity of the global estimate. In partic-
ular, in deriving the lower bounds (Theorem 6.1) we explicitly define a nonconformity
coefficient that affects the effectivity index.

The structure of the paper is as follows. In section 2 some useful notation con-
cerning DFNs is introduced; in section 3 the problem and its discrete formulation are
stated; in sections 4 and 5 suitable estimators are defined and an upper bound of
the error is provided; in section 6 the efficiency of these estimators is proved; and in
section 7 some numerical results are described.

2. Nomenclature and main assumptions. In the present work we consider
a network of fractures surrounded by an impervious rock matrix, with flow occurring
only through fractures and across fracture intersections in the normal direction. Let
us denote by $\Omega$ the DFN, composed of $N$ intersecting fractures (see Figure 1a). Each
fracture $F_i$, $i \in I = \{1, \ldots, N\}$, is a planar open polygon, with boundary $\partial F_i$, and
the boundary of $\Omega$ is $\partial \Omega = \bigcup_{i \in I} \partial F_i$. We assume that all the fractures in $\Omega$
are connected, i.e., each fracture has at least one intersection with another fracture
in the network, and we call these intersections traces, each denoted by $\Gamma_m$, with
$m \in \mathcal{M} = \{1, \ldots, M\}$. For the sake of simplicity we assume that there are no
intersections between traces and that each trace is shared by exactly two fractures;
so, if $\Gamma_m = F_i \cap F_j$, there is a bijective correspondence between the index $m$ and the
couple of indices $(i, j)$, thus allowing us to define the ordered couple $I_m = (i, j), i < j$
Let us introduce the functional space $V := V_1 \times \cdots \times V_N$, where $V_i := H^0_0(F_i)$ $\forall i \in \mathcal{I}$. For any function $g \in V$, we define the jump operator across a trace $\Gamma_m$ as $\jump{g}_{\Gamma_m} := \gamma^+_m(g_i) - \gamma^-_m(g_j)$ $\forall m \in \mathcal{M}$ and $(i, j) = \mathcal{I}_m$. Then $\jump{g}_{\mathcal{M}_i}$ is the vector of jumps of $g$ across the traces in $\mathcal{M}_i$, ordered according to trace index: $\jump{g}_{\mathcal{M}_i} := (\jump{g}_{\Gamma_{\mathcal{M}_i(1)}}, \ldots, \jump{g}_{\Gamma_{\mathcal{M}_i(M)}})$. Similarly, given a function $g_i \in V_i$, $\jump{\partial_{\mathcal{M}_i}, m}_{\mathcal{M}_i}$ is the
First of all, we define the fluxes formulation of the above problem as an optimization problem of a suitable functional.

\[ \frac{\partial g_i}{\partial n} \mid_{\mathcal{M}_i} := \left( \left[ \frac{\partial g_i}{\partial n} \right]_{\Gamma_{M_i(1)}}, \ldots, \left[ \frac{\partial g_i}{\partial n} \right]_{\Gamma_{M_i(M_i)}} \right). \]

3. Problem formulation. Let us denote the unknown hydraulic head in \( \Omega \) as \( h = (h_1, \ldots, h_N) \in V \), where \( h_i \in V_i \) for \( i = 1, \ldots, N \) is the hydraulic head on \( F_i \). Then, in a simplified setting, using homogeneous Dirichlet boundary conditions, the DFN problem can be stated as follows: find \( h \in V \) such that \( \forall i \in I \)

\[ (\nabla h_i, \nabla v)_{F_i} = (f_i, v)_{F_i} + \left( \left[ \frac{\partial h_i}{\partial n} \right]_{\mathcal{M}_i}, \gamma_{\mathcal{M}_i} (v) \right)_{\mathcal{M}_i}, \quad \forall v \in V_i, \]

where \( f_i \in L^2(F_i) \), \( \forall i \in I \) is a function representing source terms on the fracture. At fracture intersections, additional matching conditions are added, enforcing continuity of the hydraulic head and conservation of fluxes: \( \forall m \in \mathcal{M}, I_m = (i, j) \)

\[ \gamma_{\Gamma_m}^i (h_i) - \gamma_{\Gamma_m}^{j} (h_j) = 0, \]

\[ \left[ \frac{\partial h_i}{\partial n} \right]_{\Gamma_m} + \left[ \frac{\partial h_j}{\partial n} \right]_{\Gamma_m} = 0. \]

3.1. Formulation as an optimization problem. We now aim at a different formulation of the above problem as an optimization problem of a suitable functional. First of all, we define the fluxes (see Figure 1b)

\[ \forall i \in I, \forall m \in \mathcal{M}_i, w^m_i := \left[ \frac{\partial h_i}{\partial n} \right]_{\Gamma_m} \in H^{-1/2}(\Gamma_m) \]

\[ \forall i \in I, \quad u_i := (u_i^{M_i(1)}, \ldots, u_i^{M_i(M_i)}) \in \prod_{m \in \mathcal{M}_i} H^{-1/2}(\Gamma_m) := U_i, \]

\[ U := (u_1, \ldots, u_N) \in \prod_{i \in I} U_i := U. \]

In general, an element \( u \) of \( U \) is a \( 2(\#\mathcal{M}) \)-tuple of functions each belonging to \( H^{-1/2}(\Gamma_m) \) for some \( m \in \mathcal{M} \). For all \( u \in U \), we indicate by \( u_i \) the \( M_i \)-tuple of functions in \( u \) which are defined on the traces lying on fracture \( F_i \). The component of \( u \) related to the trace \( \Gamma_m \) and the fracture \( F_i \) is denoted by \( w^m_i \in H^{-1/2}(\Gamma_m) \).

Moreover, for any \( u \in U \) we set \( \{w\}\mid_{\Gamma_m} = w^m_i + w^m_j \forall m \in \mathcal{M} \) with \( I_m = (i, j) \) and indicate by \( \{w\}\mid_{\mathcal{M}_i} \) the vector whose \( k \)th component is \( \{w\}\mid_{\Gamma_{M_i(k)}} \). Let us define by \( U_i^* \) and \( U^* \) the dual spaces of \( U_i \) and \( U \), respectively.

Let us define the operator \( \mathcal{H} : U \rightarrow V \), which associates to each vector \( u \in U \) a vector \( \mathcal{H}(u) = (h^w_1, \ldots, h^w_N) \) of solutions to a Darcy’s problem on each fracture independently, that is,

\[ (\nabla h_i^w, \nabla v_i)_{F_i} = (f_i, v_i)_{F_i} + \left( w_i, \gamma_{\mathcal{M}_i} (v_i) \right)_{\mathcal{M}_i}, \quad \forall i \in I, \forall v_i \in V_i. \]

Moreover, for each \( m \in \mathcal{M} \), we define the constrained functional \( J_m : U \rightarrow \mathbb{R} \) such that

\[ J_m(u) = \|h^w\|_{\mathcal{M}_i}^2 H^{1/2}(\Gamma_m) + \|\{w\}\mid_{\Gamma_m}^2 H^{-1/2}(\Gamma_m), \quad \text{where } h^w = \mathcal{H}(u). \]
The first term of the functional $J_m(w)$ represents the jump of the hydraulic head on the two fractures sharing the trace $\Gamma_m$: we call this functional “constrained” because we assume that these hydraulic heads satisfy equations (3.4) on the two fractures sharing $\Gamma_m$. The second term of the functional represents the flux conservation at the trace $\Gamma_m$.

We can define the global (constrained) functional $J : U \to \mathbb{R}$ such that $J(w) = \sum_{m \in \mathcal{M}} J_m(w)$. We formulate the problem (3.1)–(3.3) as a constrained optimization problem:

\[
(3.6) \quad \text{find } u \in U \text{ such that } u = \arg \min_{w \in U} J(w).
\]

The functional $J(w)$ is positive $\forall w \in U \setminus \{u\}$ and $J(u) = 0$.

### 3.2. Equivalence with an elliptic differential problem.

We recall here the equivalence between problem (3.6) and a system of PDEs involving $h$, $u$, and an auxiliary pressure $p \in V$ (see [7, Proposition 2.4]).

**Proposition 3.1.** The unique minimum of the functional $J(w)$ corresponds to the first order stationary conditions $\forall i \in I$:

\[
(3.7) \quad \langle \{u\}, \mu_i \rangle_{\mathcal{M}_i} = -\langle \gamma_{\mathcal{M}_i} (p_i), \mu_i \rangle_{\mathcal{M}_i} \forall \mu_i \in U^+_i,
\]

\[
(3.8) \quad (\nabla p_i, \nabla q_i)_{F_i} = \langle [h]_{\mathcal{M}_i}, \gamma_{\mathcal{M}_i} (q_i) \rangle_{\mathcal{M}_i} \forall q_i \in V_i,
\]

\[
(3.9) \quad (\nabla h_i, \nabla v_i)_{F_i} = (f_i, v_i)_{F_i} + \langle u_i, \gamma_{\mathcal{M}_i} (v_i) \rangle_{\mathcal{M}_i} \forall v_i \in V_i.
\]

**Remark 1.** From (3.2)–(3.3), we see that $[h]_{\mathcal{M}_i}$ is the null vector as well as $\{\{u\}\}$. Therefore, the exact solution of (3.8) corresponds to $p_i \equiv 0 \forall i \in I$.

We now want to find a suitable elliptic operator that describes our problem. We define the functional spaces $L := V \times V \times U$ and $L^* := V \times V \times U^*$, whose norms are

\[
(3.10) \quad \|(h, p, u)\|_L := \left[ \sum_{i \in I} \left( \|h_i\|^2_{F_i} + \|p_i\|^2_{F_i} + \sum_{m \in \mathcal{M}_i} \|u_m^i\|^2_{H^{-1}(\Gamma_m)} \right) \right]^\frac{1}{2},
\]

\[
(3.11) \quad \|(v, q, \mu)\|_{L^*} := \left[ \sum_{i \in I} \left( \|v_i\|^2_{F_i} + \|q_i\|^2_{F_i} + \sum_{m \in \mathcal{M}_i} \|\mu_m^i\|^2_{H^1(\Gamma_m)} \right) \right]^\frac{1}{2}.
\]

We can define the bilinear continuous operator $\mathcal{L} : L \times L^* \to \mathbb{R}$ such that

\[
(3.12) \quad \mathcal{L} ((h, p, u), (v, q, \mu)) := \sum_{i \in I} \left\{ \langle \nabla h_i, \nabla v_i \rangle_{F_i} - \langle u_i, \gamma_{\mathcal{M}_i} (v_i) \rangle_{\mathcal{M}_i} + \langle \nabla p_i, \nabla q_i \rangle_{F_i} - \langle [h]_{\mathcal{M}_i}, \gamma_{\mathcal{M}_i} (q_i) \rangle_{\mathcal{M}_i} + \langle \gamma_{\mathcal{M}_i} (p_i), \{u\} \rangle_{\mathcal{M}_i} + \langle \mu_i \rangle_{\mathcal{M}_i} \right\}.
\]

Using this definition, the system of equations of Proposition 3.1 can be written in compact form as

\[
(3.13) \quad \forall (v, q, \mu) \in L^*, \quad \mathcal{L} ((h, p, u), (v, q, \mu)) = \sum_{i \in I} (f_i, v_i)_{F_i}.
\]

This problem has a unique solution since it is equivalent to (3.1)–(3.3); thus applying the Nečas theorem (see, for example, [20, Theorem 3.3]), we can say that $\mathcal{L}$ satisfies an inf-sup condition:

\[
(3.14) \quad \exists \beta > 0 : \|(h, p, u)\|_L \leq \beta \sup_{(v, q, \mu) \in L^*} \frac{\mathcal{L} ((h, p, u), (v, q, \mu))}{\|(v, q, \mu)\|_{L^*}}.
\]
3.3. Problem discretization. An important advantage of the formulation introduced in the previous sections is that the discretization of each fracture does not have to conform to the traces; i.e., triangles can freely cross traces. In the following, we assume that each fracture is meshed by a good quality triangulation $\mathcal{T}_{\delta i}$ [11]. Let $\mathcal{T}_{\delta} = \bigcup_{i \in \mathcal{I}} \mathcal{T}_{\delta i}$ be the set of all the triangles on the DFN. Let $\mathcal{V}_{\delta}$ be the set of the vertices of the triangles in $\mathcal{T}_{\delta}$, and let $\mathcal{E}_{\delta}$ be the set of all the edges of the triangles in $\mathcal{T}_{\delta}$. $\mathcal{V}_{\delta i}$ and $\mathcal{E}_{\delta i}$ coherently are the subsets of $\mathcal{V}_{\delta}$ and $\mathcal{E}_{\delta}$ containing the objects defined on fracture $F_i$. For all $T \in \mathcal{T}_{\delta}$, we indicate by $\bar{T}$ the interior of $T$, by $\mathcal{M}_T$ the set of indices of those traces having nonempty intersection with $\bar{T}$, and by $\ell_T^m$ the segment $\Gamma_m \cap \bar{T}$, $\forall m \in \mathcal{M}_T$. Coherently, for any given $\sigma \in \mathcal{E}_{\delta}$ we indicate by $\mathcal{M}_\sigma$ the set of those $m \in \mathcal{M}$ such that $|\Gamma_m \cap \sigma| \neq \emptyset$. Moreover, on each trace $\Gamma_m$ shared by two fractures $F_i$ and $F_j$, we fix two discretizations $\Lambda_{m,i}$ and $\Lambda_{m,j}$ defined on the two fractures, respectively. In the following, the symbol $\delta g$ denotes the diameter of an arbitrary geometrical object $g$.

To solve the minimization problem in (3.6) we start by discretizing (3.13). Let us define the following finite-dimensional subspaces:

$$V_{\delta i} \subset V_i \forall i \in \mathcal{I}, \quad U_{\delta i}^m \subset L^2(\Gamma_m) \subset H^{-\frac{1}{2}}(\Gamma_m) = U_{\delta i}^m \forall i \in \mathcal{I}, m \in \mathcal{M}_i,$$

and let us set $U_{\delta i} := \prod_{m \in \mathcal{M}_i} U_{\delta i}^m \forall i \in \mathcal{I}$, $U_{\delta} := \prod_{i \in \mathcal{I}} U_{\delta i}$, $V_{\delta} := \prod_{i \in \mathcal{I}} V_{\delta i}$. Our discrete problem is to find $h_{\delta}, p_{\delta}, u_{\delta} \in U_{\delta}$ and $u_{\delta} \in U_{\delta}$ such that

$$\mathcal{L}((h_{\delta}, p_{\delta}, u_{\delta}), (v_{\delta}, q_{\delta}, \mu_{\delta})) = \sum_{i \in \mathcal{I}} (f_i, v_{\delta i})_{F_i} \quad \forall v_{\delta}, q_{\delta} \in V_{\delta}, \mu_{\delta} \in U_{\delta},$$

that is, to solve the following system of equations $\forall i \in \mathcal{I}$:

$$\begin{align*}
\left(\{u_{\delta}\}\right)_{\mathcal{M}_i, \mu_{\delta}} &= -\left(\gamma_{\mathcal{M}_i}, (p_{\delta i}), \mu_{\delta i}\right)_{\mathcal{M}_i} \quad \forall \mu_{\delta i} \in U_{\delta i}, \\
(\nabla p_{\delta i}, \nabla v_{\delta i})_{F_i} &= \left(\|h_{\delta}\|_{\mathcal{M}_i}, \gamma_{\mathcal{M}_i}, (v_{\delta i})\right)_{\mathcal{M}_i} \quad \forall v_{\delta i} \in V_{\delta i}, \\
(\nabla h_{\delta i}, \nabla v_{\delta i})_{F_i} &= (f_i, v_{\delta i})_{F_i} + \left(\{u_{\delta i}\}\right)_{\mathcal{M}_i} \quad \forall v_{\delta i} \in V_{\delta i}, \forall i \in \mathcal{I}.
\end{align*}$$

This is equivalent (see [7]) to minimizing a functional with the same structure of $J$ but involving $L^2(\Gamma_m)$ norms of the discrete functions $h_{\delta}$ and $u_{\delta}$. Indeed, if we define $\mathcal{H}_{\delta} : U_{\delta} \rightarrow V_{\delta}$ such that $(h_{\delta 1}, \ldots, h_{\delta N}) = \mathcal{H}_{\delta}(u_{\delta})$ is the solution vector of

$$\begin{align*}
(\nabla h_{\delta i}, \nabla v_{\delta i})_{F_i} &= (f_i, v_{\delta i})_{F_i} + \left(\{u_{\delta i}\}\right)_{\mathcal{M}_i} \quad \forall v_{\delta i} \in V_{\delta i}, \forall i \in \mathcal{I},
\end{align*}$$

then we can define, for any given $w_{\delta} \in U_{\delta}$ and any $m \in \mathcal{M}$, the functional $J_{m,\delta}$ such that

$$J_{m,\delta}(w_{\delta}) = \|\|h_{\delta}\|_{\Gamma_m}\|_{\Gamma_m}^2 + \|\{w_{\delta}\}\|_{\Gamma_m}^2\|_{\Gamma_m}^2 \quad \text{with } h_{\delta}^w = \mathcal{H}_{\delta}(w_{\delta}).$$

The system (3.16)–(3.18) is equivalent to the following minimum problem:

$$\begin{align*}
\mathbf{u}_{\delta} &= \arg \min_{w_{\delta} \in U_{\delta}} J_{\delta}(w_{\delta}) = \arg \min_{w_{\delta} \in U_{\delta}} \sum_{m \in \mathcal{M}} J_{m,\delta}(w_{\delta}).
\end{align*}$$

4. Error and error estimators. The following quantities define the error performed approximating (3.13) by (3.15):

$$\begin{align*}
e_h &= h - h_{\delta}, \\
e_p &= p - p_{\delta}, \\
e_u &= u - u_{\delta}.
\end{align*}$$
Since \((e_h, e_p, e_u) \in L\), we have the following lemma.

**Lemma 4.1.** Let \(L\) be defined by (3.12) and \(e_h, e_p, e_u\) by (4.1). Then, for any \(v_\delta, q_\delta \in V_\delta\) and \(\mu_\delta \in U_\delta, L((e_h, e_p, e_u), (v_\delta, q_\delta, \mu_\delta)) = 0\).

We define the error measure as

\[
\text{err} := \|(e_h, e_p, e_u)\|_L.
\]

The main result of section 5 is that the error measure (4.2) can be controlled by the following quantities \(\forall i \in I\).

**Residual estimator:**

\[
\eta_{R,T} := h_T \|f_i + \Delta h_\delta\|_T \quad \forall T \in T_\delta i.
\]

**Estimator for the approximation of the flux through edges:** \(\forall \sigma \in E_\delta i\),

\[
\xi_{F,\sigma} := (h_{\sigma})^{\frac{1}{2}} \left\| \frac{\partial h_\delta}{\partial \mathbf{n}_\sigma} \right\|_{\sigma} - \tilde{u}_\delta i,\sigma \right\|_{\sigma}, \text{ where } \tilde{u}_\delta i,\sigma := \begin{cases} u_{\delta i}^m & \forall m \in M_\sigma, \\ 0 & \text{elsewhere} . \end{cases}
\]

**Estimator for the nonconformity of the discretization:**

\[
\xi_{N,T}^m := (h_{\tau_T})^{\frac{1}{2}} \|u_{\tau_T}^m\|_{\tau_T} \quad \forall T \in T_\delta i, m \in M_T.
\]

**Local estimator for the pressure induced by discontinuity:**

\[
\eta_{P,T} := \|p_{\delta i}\|_T \quad \forall T \in T_\delta i.
\]

**Local estimator for the pressure induced by the unbalancing of fluxes:**

\[
\xi_{P,\lambda} := h^\frac{1}{2}_\lambda \|\gamma_{1,m}(p_{\delta i})\|_\lambda \quad \forall m \in M_i, \lambda \in \Lambda_{m,i}.
\]

**Local estimator of the minimization error:**

\[
J_{\delta,\lambda}(u_\delta) := h^\frac{1}{2}_\lambda \left( \left\| \{u_\delta\}\right\|_{\Gamma_m} \right)_\lambda + \|H_\delta\|_{\Gamma_m} \quad \forall m \in M_i, \lambda \in \Lambda_{m,i}.
\]

The symbols \(\lesssim\) and \(\simeq\) are used to compare functions with the following meaning:

\[
f \lesssim g \iff \exists C > 0: f \leq C g,
\]

\[
f \simeq g \iff \exists C, C > 0: cg \leq f \leq Cg,
\]

where all the constants are independent of the meshsize.

**5. Reliability.** This section is devoted to obtaining an a posteriori upper bound for the error norm (4.2) based on condition (3.14). After stating some auxiliary results (subsection 5.1), we obtain (Theorem 5.2) our estimate.

**5.1. Auxiliary results.** In the following, we apply the well-known properties of Clement’s pseudointerpolation operator on the fracture \(F_i, i \in I\), denoted by \(\Pi_{\delta i}\). Given a fracture \(F_i, i \in I\), let us consider a triangle \(T \in T_{\delta i}\) and an edge \(\sigma \in E_{\delta i}\). Then, for any \(v \in H_0^1(F_i)\),

\[
\|v - \Pi_{\delta i}(v)\|_T \lesssim h_T \|v\|_{\omega_T},
\]

\[
\|v - \Pi_{\delta i}(v)\|_T \lesssim \|v\|_{\omega_T},
\]

\[
\|\gamma_{\sigma}^T (v - \Pi_{\delta i}(v))\|_\sigma \lesssim (h_{\sigma})^{\frac{1}{2}} \|v\|_{\omega_{\sigma}},
\]

where all the constants are independent of the meshsize.
The following result holds.

(5.4) \[ \exists \text{ continuous linear operator preserving a.e. constant functions.} \]

Then

\[ H_\lambda \]

The following result holds.

**Theorem 5.1.** Let \( \lambda \) be a segment of length \( h_\lambda \) and \( P : \mathbb{H}^{\frac{1}{2}}(\lambda) \rightarrow L^2(\lambda) \) a continuous linear operator preserving a.e. constant functions. Then

\[ (5.4) \quad \exists C > 0 : \forall g \in \mathbb{H}^{\frac{1}{2}}(\lambda), \| g - Pg \|_{0, \lambda} \leq C h_\lambda^2 |g|_{\frac{1}{2}, \lambda}. \]

**5.2. Upper bound.** In this section we derive an upper bound for the error.

**Theorem 5.2.** Let \( e_h, e_p, e_u \) be defined by (4.1), and let all the quantities defined in (4.3)–(4.8) be given. Then

\[ err \lesssim \sum_{i \in I} \left[ \sum_{T \in T_i} \left( |\eta_{RT} + \eta_{PT} + \sum_{m \in M_T} \xi_m^{MT} \right) + \sum_{\sigma \in E_i} \xi_m^{STT} + \sum_{m \in M_i} \sum_{\lambda \in \Lambda_{m, i}} \left( \xi_m^{ST} + J_{\delta, \lambda}(u_\delta) \right) \right]. \]

**Proof.** From (3.14) we have

\[ err = \| (e_h, e_p, e_u) \|_L \lesssim \sup_{(v, q, \mu) \in L^*} \frac{\mathcal{L}((e_h, e_p, e_u), (v, q, \mu))}{\| (v, q, \mu) \|_{L^*}}. \]

From Lemma 4.1 we know that, for any given \( v_\delta, q_\delta \in V_\delta \) and \( \mu_\delta \in U_\delta \),

\[ \mathcal{L}((e_h, e_p, e_u), (v, q, \mu)) = \sum_{i \in I} \left( \langle \nabla(h_i - h_\delta), \nabla(v_i - v_\delta) \rangle_{T_i} - \langle u_i - u_\delta, \gamma_{M_i}(v_i - v_\delta) \rangle_{M_i} \right) \]

\[ + \langle \nabla(p_i - p_\delta), \nabla(q_i - q_\delta) \rangle_{F_i} - \langle [h - h_\delta], [\gamma_{M_i}(q_i - q_\delta) \rangle_{M_i} \]

\[ + \langle \gamma_{M_i}(p_i - p_\delta), (u_i - u_\delta) \rangle_{M_i} + \langle \mu_i - \mu_\delta \rangle_{M_i} \right). \]

We now proceed by estimating separately the terms involving different test functions. Let \( i \in I \) be fixed:

- **Terms with test function** \( v_i - v_\delta \). Since \( h = H(u) \) (thus \( h_i \) and \( u_i \) are linked by (3.9)), applying Green’s formula on \( T_\delta \), we obtain

\[ \langle \nabla(h_i - h_\delta), \nabla(v_i - v_\delta) \rangle_{T_i} = \sum_{T \in T_\delta} (f_i + \Delta h_\delta, v_i - v_\delta)_T - \sum_{\sigma \in E_i} \left( \frac{\partial h_\delta}{\partial n_\sigma}, \gamma_{\sigma} (v_i - v_\delta) \right)_{\sigma} \]

\[ + \sum_{m \in M_i} \langle u_{\delta i}^m, \gamma_{m i}^i (v_i - v_\delta) \rangle_{m_i}. \]
Then, since $\left[\frac{\partial h_i^\sigma}{\partial n_\sigma}\right]_\sigma \in L^2(\sigma)$, $u_{\delta i}^m \in L^2(\Gamma_m) \subset H^{-\frac{1}{2}}(\Gamma_m)$, $\gamma_i^\sigma(v_i - v_{\delta i}) \in H^\frac{1}{2}(\sigma) \subset L^2(\sigma)$, $\gamma_i^T_m(v_i - v_{\delta i}) \in H^\frac{1}{2}(\Gamma_m) \subset L^2(\Gamma_m)$, it is possible to write the duality product on each trace as a scalar product in $L^2$:

$$
- \sum_{\sigma \in E_\delta} \left\langle \left[\frac{\partial h_i^\delta}{\partial n_\sigma}\right]_\sigma, \gamma_i^\delta(v_i - v_{\delta i}) \right\rangle + \sum_{m \in M_i} \left\langle u_{\delta i}^m, \gamma_i^T_m(v_i - v_{\delta i}) \right\rangle_{\Gamma_m}
= \sum_{\sigma \in E_\delta} \left( \tilde{u}_{\delta i, \sigma} - \left[\frac{\partial h_i^\delta}{\partial n_\sigma}\right]_\sigma \right), \gamma_i^\delta(v_i - v_{\delta i}) + \sum_{m \in M_T} \left( u_{\delta i}^m, \gamma_i^T_m(v_i - v_{\delta i}) \right)_{\ell_T^T}.
$$

Then, taking $v_{\delta i} = \Pi_{\delta i}(v_i)$ and using inequalities (5.1) and (5.3),

$$(\nabla(h_i - h_{\delta i}), \nabla(v_i - v_{\delta i}))_{F_i} = \left\langle \left[\frac{\partial h_i}{\partial n_\sigma}\right]_\sigma, \gamma_i^\delta(v_i - v_{\delta i}) \right\rangle_{M_i}
\leq \left\{ \sum_{T \in T_\delta} \left( h_{\delta i} + \Delta h_{\delta i} \right)_T + \sum_{m \in M_T} \left( h_{\delta i}^m, u_{\delta i}^m \right)_{\ell_T^T} + \sum_{\sigma \in E_\delta} \left( \left[\frac{\partial h_i^\delta}{\partial n_\sigma}\right]_\sigma - \tilde{u}_{\delta i, \sigma} \right), \gamma_i^\delta(v_i - v_{\delta i}) \right\}_{\ell_T^T}.
$$

- **Terms with test function $q_i - q_{\delta i}$.** Using (3.8), Green’s formula applied on $T_{\delta i}$, and the fact that $\|h\|_{M_i} = 0$ and $p_i = 0$,

$$(\nabla(p_i - p_{\delta i}), \nabla(q_i - q_{\delta i}))_{F_i} = \left\langle \left[\frac{\partial h_i}{\partial n_\sigma}\right]_\sigma, \gamma_i^\delta(q_i - q_{\delta i}) \right\rangle_{M_i}
= \sum_{T \in T_\delta} \left( -\nabla p_{\delta i}, \nabla(q_i - q_{\delta i}) \right)_T + \sum_{m \in M_i} \left( \left[\frac{\partial h_i^\delta}{\partial n_\sigma}\right]_\sigma, \gamma_i^\delta(q_i - q_{\delta i}) \right)_{\Gamma_m}.
$$

For any given $m \in M_i$, we introduce a discretization $\Lambda_{m,i}$ writing

$$( -\left[\frac{\partial h_i}{\partial n_\sigma}\right]_\sigma, \gamma_i^\delta(q_i - q_{\delta i}) \right)_{\Gamma_m} \leq \sum_{\lambda \in \Lambda_{m,i}} \left\| h_{\delta i}^\sigma \right\|_{\Gamma_m, \lambda} \left\| \gamma_i^\delta \right\|_{\Gamma_m, \lambda} \left\| q_i - q_{\delta i} \right\|_{\Lambda} ;
$$

then, choosing $q_{\delta i} = \Pi_{\delta i}(q_i)$ and using inequalities (5.1) and (5.3),

$$(\nabla(p_i - p_{\delta i}), \nabla(q_i - q_{\delta i}))_{F_i} = \left\langle \left[\frac{\partial h_i}{\partial n_\sigma}\right]_\sigma, \gamma_i^\delta(q_i - q_{\delta i}) \right\rangle_{M_i}
\leq \left( \sum_{T \in T_\delta} \left\| p_{\delta i} \right\|_T + \sum_{m \in M_i} \sum_{\lambda \in \Lambda_{m,i}} h_{\lambda}^\sigma \left\| h_{\delta i}^\sigma \right\|_{\Gamma_m, \lambda} \right) \left\| q_i - q_{\delta i} \right\|_{F_i}.
$$

- **Term with test function $\mu_i - \mu_{\delta i}$.** Using (3.7), and since $\gamma_i^T_m(p_{\delta i})$, $\mu_i^m \in H^\frac{1}{2}(\Gamma_m) \subset L^2(\Gamma_m)$, $u_{\delta i}^m \in L^2(\Gamma_m) \subset H^{-\frac{1}{2}}(\Gamma_m)$, we obtain the following by rewriting the duality product as a scalar product in $L^2(\Gamma_m)$ and using discretization $\Lambda_{m,i}$:

$$(\gamma_i^\sigma(p_i - p_{\delta i}) + \left\{ u_i - u_{\delta i} \right\}_{M_i}, \mu_i - \mu_{\delta i})_{M_i}
= \sum_{m \in M_i} \sum_{\lambda \in \Lambda_{m,i}} \left( -\gamma_i^T_m(p_{\delta i}) \right)_{\Gamma_m} + \left( \left\{ u_{\delta i} \right\}_{\Gamma_m} \right)_{\Lambda} \left( \left\| u_i^m - u_{\delta i}^m \right\|_{\Gamma_m} \right)_{\Lambda} \left\| \mu_i^m - \mu_{\delta i}^m \right\|_{\ell_T^T}.
$$
where the last estimate is obtained by supposing \( \mu_{\delta}^m \) is the image of \( \mu_{\delta}^m \) through a linear continuous operator that preserves constants by applying Theorem 5.1 and since

\[
\| \mu_{\delta}^m \|_{H^1(\Gamma_m)} \leq \| \mu_{\delta}^m \|_{H^1(\Gamma_m)} = \inf_{v \in H^1(\Gamma_m)} \| v \|_{L^1(\Gamma_m)}
\]

where \( \omega_{\Gamma_m,i} \) is a subregion of \( F_i \) having \( \Gamma_m \) on its boundary.

The proof is concluded since \( \forall i \in I \) and \( \forall m \in M_i \)

\[
\| v \|_{F_i} \leq \| (v, q, \mu) \|_{L^*.} \quad \| q \|_{F_i} \leq \| (v, q, \mu) \|_{L^*.} \quad \| \mu_{\delta}^m \|_{1, \Gamma_m} \leq \| (v, q, \mu) \|_{L^*.}
\]

For the sake of notational simplicity, we define the global estimator

\[
est := \sum_{i \in I} \left[ \sum_{T \in T_i} \left( \eta_{R,T} + \eta_{P,T} + \sum_{m \in M_T} \xi_{NC,T}^m \right) + \sum_{\sigma \in E_i} \xi_{F,\sigma}^m \right.
\]

\[+ \sum_{m \in M_i} \sum_{\lambda \in \Lambda_{m,i}} \left( \xi_{P,\lambda} + J_{\delta,\lambda}(u_\delta) \right) \].

6. Efficiency of the a posteriori error estimate. In this section we prove the efficiency of the estimators presented in Theorem 5.2; i.e., we show that for the a posteriori error estimator of Theorem 5.2 we can write a lower bound in terms of a multiple of the error norm defined by (4.2).

From now on, \( \forall i \in I \) we assume that the discretization \( \Lambda_{m,i} \) which was fixed in subsection 3.3 is the one induced on \( \Gamma_m \) by the triangulation \( T_{\delta} \), that is, \( \Lambda_{m,i} = \bigcup_{T \in T_{\delta}} T_{\nu,T}^p \). For any triangle \( T \in T_{\delta} \), the following nonconformity measure can be defined:

\[
h_{NC,T} := \sum_{m \in M_T} h_{\nu,T}^m.
\]

Such a quantity is zero for all triangles having an empty intersection with all traces and is less than or equal to \# \( M_T h_T \) for those intersecting some of them. It is not too restrictive to suppose \( h_{NC,T} < 1 \), assuming that the problem is written in a nondimensional way. The results in subsections 6.1, 6.2, and 6.3 together prove the following theorem.

**Theorem 6.1.** Let \( \est \) be defined by (5.5), let \( e_h, e_u, \) and \( e_p \) be defined by (4.1), and let \( h_{NC,T} \) be defined by (6.1) \( \forall T \in T_{\delta} \). Then, if \( h_{NC,T} < 1 \) \( \forall T \in T_{\delta} \),

\[
est \leq \| e_p \| + C_{NC} \left[ \max_{\sigma \in E_i} \left\{ 1, h_\sigma \right\} \left( \| e_h \| + \sum_{m \in M} \| e_u \|_U \right) + \max_{T \in T_{\delta}} h_T \| f_T - f_T \| \right],
\]

where \( f_T \) is the mean of \( f_i \) on triangle \( T \in T_{\delta} \) and

\[
C_{NC} := \max_{T \in T_{\delta}} \left( \frac{1 + h_{NC,T}}{1 - h_{NC,T}} \right).
\]

**Remark 2.** We remark that the efficiency of the a posteriori estimate depends on the nonconformity of the triangulation through \( C_{NC} \), which tends to 1 by refining the mesh. In a nondimensional formulation of the problem, it is, however, always possible to ask that the coarsest considered triangulation satisfy \( h_{NC,T} \leq \frac{1}{2} \) (thus having \( C_{NC} \leq 3 \).
6.1. Auxiliary results. We apply classical results about suitable cut-off functions [25], which exploit the properties of special polynomial functions with compact support, called bubble functions.

Given \( i \in T \) and any triangle \( T \subset T_i \), let us denote by \( b_T \) the triangle bubble function as defined in [25]. It has the following properties:

\[
\text{supp } b_T = T, \quad 0 \leq b_T \leq 1, \quad \max_{x \in T} b_T(x) = 1, \quad (b_T, 1)_T = \frac{9}{20} |T|,
\]

from which, since \( b_T \in H^1_0(T) \), the following estimates can be obtained (see [25, Lemma 1.3]):

\[
(b_T, v)_T = \frac{1}{2} \| b_T \|_T^2 \leq (b_T, 1)_T \leq \frac{9}{20} |T| \leq h_T^2 \Rightarrow \| b_T \|_T \lesssim h_T,
\]

\[
\| \nabla b_T \|_T \lesssim h_T^{-1} \| b_T \|_T \Rightarrow \| \nabla b_T \|_T \lesssim 1.
\]

Let \( l \subset T \) be a segment not necessarily intersecting \( \partial T \), and let \( L \) be its prolongation up to \( \partial T \). Then, since \( \gamma_L(\omega_T) \in H^1_0(L) \) and \( h_L \leq h_T \), applying the continuity of the trace operator on \( L \), we have

\[
\| \gamma_L(\omega_T) \|_{H^1_0(L)} \lesssim \| \gamma_L(b_T) \|_{H^1_0(T)} \lesssim \| \gamma_L(b_T) \|_{H^1_0(L)} \lesssim \| \nabla b_T \|_T \lesssim 1.
\]

All the constants depend on the quality of the considered triangle, namely, on the minimum of its angles. It is possible to prove the following useful result [24, Lemma 4.1].

**Lemma 6.2.** Let \( i \in T \), let \( T \in T_i \), and let \( b_T \) be the bubble function on \( T \). Let \( P(T) \subset H^1(T) \) be a finite-dimensional space. Then, for any given \( v \in P(T) \),

\[
||v||_T^2 \leq (b_T, v^2)_T, \quad ||v b_T||_T \leq ||v||_T,
\]

\[
||b_T v||_T \leq h_T^{-1} ||v||_T.
\]

We now consider a segment \( \sigma \subset F_i \) shared by two triangles \( R \) and \( L \) belonging to a regular triangulation, that is, such that \( h_R \simeq h_L \simeq h_\sigma \). We denote by \( b_\sigma \) the side bubble function of \( \sigma \) as defined in [25]. It has the following properties:

\[
\text{supp } b_\sigma = \omega_\sigma, \quad 0 \leq b_\sigma \leq 1, \quad \max_{x \in \omega_\sigma} b_\sigma = 1, \quad (\gamma_\sigma(b_\sigma), 1)_\sigma = \frac{2}{3} h_\sigma \simeq h_\sigma,
\]

\[
\forall T \in \{ R, L \}, \quad (b_\sigma, 1)_T = \frac{1}{3} |T|,
\]

from which, since \( b_\sigma \in H^1_0(\omega_\sigma) \),

\[
\| \gamma_\sigma(b_\sigma) \|_{H^1(\omega_\sigma)}^2 = (\gamma_\sigma(b_\sigma), \gamma_\sigma(b_\sigma))_{\omega_\sigma} \leq (\gamma_\sigma(\sigma), 1)_{\sigma} \Rightarrow \| \gamma_\sigma(b_\sigma) \|_{\omega_\sigma} \lesssim h_\sigma^2,
\]

\[
\| b_\sigma \|_{\omega_\sigma} = (b_\sigma, b_\sigma)_{\omega_\sigma} \leq (b_\sigma, 1)_{\omega_\sigma} \Rightarrow \| b_\sigma \|_{\omega_\sigma} \lesssim h_\sigma,
\]

\[
\| \nabla b_\sigma \|_{\omega_\sigma} \lesssim h_\sigma^{-1} \| b_\sigma \|_{\omega_\sigma} \Rightarrow \| \nabla b_\sigma \|_{\omega_\sigma} \lesssim 1.
\]

Let \( l \subset \omega_\sigma \) be a segment that does not necessarily intersect \( \partial \omega_\sigma \), and let \( L \) be its straight prolongation whose extrema intersect \( \partial \omega_\sigma \). Then, since \( b_\sigma \in H^1_0(L) \) and \( h_L \leq h_\sigma \), by applying the continuity of the trace operator on \( L \),

\[
\| \gamma_L(b_\sigma) \|_{H^1_0(L)} \lesssim \| \gamma_L(\omega_T) \|_{H^1_0(T)} \lesssim \| \gamma_L(b_\sigma) \|_{H^1_0(L)} \lesssim \| \nabla b_\sigma \|_{\omega_\sigma} \lesssim 1.
\]
Again, constants depend on the minimum angle in $\omega_{\sigma}$. The following lemma, analogous to Lemma 6.2, also involves the continuation operator defined in [25], which extends a function from a side $\sigma$ of a triangle $T$ to the whole triangle. We denote this operator by $C_T : L^\infty(E) \to L^\infty(T)$. The following lemmas can be proved using [24, Lemma 4.1] and the techniques in [25].

**Lemma 6.3.** Let $\sigma \subset F_i$ be a segment shared by two triangles $R$ and $L$, and let $b_\sigma$ be its bubble function defined on the union of the two triangles. Let $P(\sigma) \subset \mathbb{H}_h(\sigma)$ be a finite-dimensional space. Then, for any given $v \in P(\sigma)$ and any triangle $T \in \{R, L\}$,

\[ ||v||^2_\sigma \lesssim (v, v_{\gamma_\sigma}(b_\sigma))_\sigma, \]

\[ ||vb_\sigma||_\sigma \leq ||v||_\sigma. \]

\[ \|C_T(v) b_\sigma\|_T \lesssim \|v\|^{\frac{1}{2}}_\sigma. \]

\[ \|C_T(v) b_\sigma\|_T \lesssim \|v\|^{\frac{1}{2}}_\sigma. \]

**6.2. Efficiency of estimators.** In this subsection we report the results about the efficiency of the estimators. We show only the proof of Proposition 6.8, which is responsible for the introduction of the constant $C_{NC}$. We refer the reader to the supplementary material for the other proofs. These results, together with the ones in the following subsection, prove Theorem 6.1. Lemmas 6.4 and 6.5 are used in the proofs of the subsequent propositions.

**Lemma 6.4.** Let $u \in U$, $u_\delta \in U_\delta$ be the solutions of (3.6) and (3.21). Let $h = H(u)$ and $h_\delta = H_\delta(u_\delta)$. Then, for any $i \in I, v \in V_i$,

\[ \sum_{\sigma \in E_{\delta i}} \left( \frac{\partial h_\delta \sigma}{\partial n_{\sigma}}, \gamma_\sigma(v) \right)_\sigma = \sum_{T \in T_{\delta i}} (f_i + \Delta h_\delta, v)_T + \langle u_i, \gamma_{\mathcal{M}_i}(v) \rangle_{\mathcal{M}_i} + \langle \nabla(h_\delta - h_i), \nabla v \rangle_{F_i}. \]

**Lemma 6.5.** Let $f$ be the vector of forcing terms in problem (3.1) and $f_T = \frac{1}{|T|}(f_i, 1)_T$ its mean value on each $T \in T_{\delta i} (i \in I)$. Then

\[ \|f_T + \Delta h_\delta\|_T \lesssim \|f_T - f_T\|_T + \frac{1}{h_T} \left[ \|h_i - h_\delta\|_T + \sum_{m \in \mathcal{M}_i} \|u^m_i - u^m_\delta\|_{L^2(T)} + \frac{1}{h_T} (\xi_{NC,T}^m + \epsilon_{\delta i}^m) \right]. \]

**Proposition 6.6** (efficiency of $\eta_{R,T}$). Let $i \in I, T \in T_{\delta i}$. Let $\eta_{R,T}$ be the estimator defined by (4.3). Then

\[ \eta_{R,T} \lesssim \|h_i - h_\delta\|_T + \sum_{m \in \mathcal{M}_i} \left( \|u^m_i - u^m_\delta\|_{L^2(T)} + \frac{1}{h_T} (\xi_{NC,T}^m + \epsilon_{\delta i}^m) \right) + h_T \|f_T - f_T\|_T. \]

**Proposition 6.7** (efficiency of $\xi_{F,\sigma}$). Let $i \in I, \sigma \in E_{\delta i}$, let $\xi_{F,\sigma}$ be defined by (4.4), and let $\xi_{NC,T}^m$ be defined by (4.5) and $\eta_{R,T}$ by (4.3). Then

\[ \xi_{F,\sigma} \lesssim \sum_{T \in \omega_\sigma} \left( \|h_i - h_\delta\|_T + h_\sigma \eta_{R,T} + \sum_{m \in \mathcal{M}_i} \xi_{NC,T}^m \right) + \sum_{m \in \mathcal{M}_i} \|u^m_i - u^m_\delta\|_{L^2(T)} + \frac{1}{h_T} (\xi_{\Gamma m \cap \delta i}^m + \epsilon_{\delta i}^m). \]

**Proposition 6.8** (efficiency of $\xi_{NC,T}^m$). Let $i \in I, T \in T_{\delta i}$, and $m \in M_T$, and let $\xi_{NC,T}^m$ be the estimator defined by (4.5). Then, assuming that $u^m_\delta$ has a finite number of jumps in $E_T^m$,

\[ \xi_{NC,T}^m \lesssim \|u^m_i - u^m_\delta\|_{L^2(T)} + \|h_i - h_\delta\|_T + h_T \eta_{R,T}. \]
Proof. First, suppose $u^m_{\delta i}$ is continuous on $\ell^m_T$. Let $R, L \subset T$ be two triangles lying in the interior of $T$ and sharing $\ell^m_T$ as a side. Let $b_{EP}$ be the bubble function of $\ell^m_T$ having support on $\omega_{EP} = R \cup L \subset T$, and let $C_R$ and $C_L$ be the continuation operators of $R$ and $L$, respectively. Let $w_{EP}$ be the function such that $w_{EP} \big|_{E} := C_E (u^m_{\delta i}) b_{EP}$ \( \forall E \in \{R, L\} \). Since $C_R (u^m_{\delta i})$ and $C_L (u^m_{\delta i})$ belong to a finite-dimensional subspace, we can apply (6.8) on the two triangles $R$ and $L$, obtaining

$$\|u^m_{\delta i}\|^2_{\ell^m_T} \leq \left< u^m_{\delta i}, \gamma^i_{EP} (w_{EP}) \right>_{\ell^m_T}.$$ 

Since $u^m_{\delta i} \in L^2(\ell^m_T) \subset H^{-\frac{1}{2}}(\ell^m_T)$ and $\gamma^i_{EP} (w_{EP}) \in H^\frac{1}{2}(\ell^m_T)$, we can rewrite the scalar product above as a duality product. Then, adding and subtracting $u^m_{\delta i}$,

$$\|u^m_{\delta i}\|^2_{\ell^m_T} \leq \left< u^m_{\delta i}, \gamma^i_{EP} (w_{EP}) \right>_{\ell^m_T} = \left< u^m_{\delta i} - u^m_{\delta i}, \gamma^i_{EP} (w_{EP}) \right>_{\ell^m_T} + \langle \nabla h_i, \nabla w_{EP} \rangle_{\omega_{EP}} - (f_i, w_{EP})_{\omega_{EP}} = \left< u^m_{\delta i} - u^m_{\delta i}, \gamma^i_{EP} (w_{EP}) \right>_{\ell^m_T} + \langle \nabla h_i, \nabla w_{EP} \rangle_{\omega_{EP}} - (f_i, w_{EP})_{\omega_{EP}} = \langle u^m_{\delta i} - u^m_{\delta i}, \gamma^i_{EP} (w_{EP}) \rangle_{\ell^m_T} + \|h_i - h_{\delta i}\|_{\omega_{EP}} + \|f_i - \Delta h_{\delta i}, w_{EP} \|_{\omega_{EP}} \leq \|u^m_{\delta i} - u^m_{\delta i}\|_{\ell^m_T} + \|f_i + \Delta h_{\delta i}, w_{EP} \|_{\omega_{EP}} \|w_{EP}\|_{\omega_{EP}} \|w_{EP}\|_{\omega_{EP}} \times \|\gamma^i_{EP} (w_{EP})\|_{\ell^m_T},$$

where Green’s formula has been applied, using the fact that there are no jumps of $\nabla h_{\delta i}$ inside $\omega_{EP}$. Using the continuity of the trace operator and (6.9), we obtain, \( \forall E \in \{R, L\} \),

$$\|\gamma^i_{EP} (w_{EP})\|_{\ell^m_T} \leq \|w_{EP}\|_{E} = \|C_E (u^m_{\delta i}) b_{EP}\|_{E} \leq \|h_{\delta i}\|^\frac{3}{2}_{\ell^m_T} u^m_{\delta i} \|_{\ell^m_T},$$

and, since $h_{EP} \leq h_T$,

$$\|w_{EP}\|_{E} = \|C_E (u^m_{\delta i}) b_{EP}\|_{E} \leq \|h_{\delta i}\|^\frac{3}{2}_{\ell^m_T} u^m_{\delta i} \|_{\ell^m_T} \leq h_T h_{\delta i}^\frac{3}{2} u^m_{\delta i} \|_{\ell^m_T}. $$

The thesis comes from the definitions of $\eta_{R,T}$, $\xi^m_{NC,T}$ and from $\|w_{EP}\|_{\omega_{EP}} \leq \|\|_{T}$. If $u^m_{\delta i}$ has some jumps, it is sufficient to apply this procedure on each of the subsegments of $\ell^m_T$ upon which it is continuous. \( \Box \)

**Proposition 6.9 (efficiency of $\eta_{R,T}$ and $\xi^i_{P,T,m}$).** Let $i \in I$, $T \in \tau_{\delta i}$. Then

$$\eta_{R,T} = \|p_i - p_{\delta i}\|_{T}.$$ 

Moreover, let $m \in \mathcal{M}_i$, $\lambda \in \Lambda_{m,i}$. Then

$$\xi^i_{P,\lambda} \leq \|p_i - p_{\delta i}\|_{\omega_{\lambda}},$$

where $\omega_{\lambda}$ is the union of two triangles having $\lambda$ as one of their sides.

**Proposition 6.10 (efficiency of $J^i_{R,\lambda}$).** Let $u_{\delta i}$ be the solution of (3.21), $h_{\delta i} = \mathcal{H}_{\delta}(u_{\delta i})$. Let $i \in I$, $m \in \mathcal{M}_i$, and $\lambda \in \Lambda_{m,i}$, and let $J^i_{R,\lambda}(u_{\delta i})$ be the quantity defined by (4.8). Then, if $\Gamma_m = F_i \cap F_j$,

$$J^i_{R,\lambda} \leq \|h_i - h_{\delta i}\|_{F_i} + \|h_j - h_{\delta j}\|_{F_j} + \|u^m_{\delta i} - u^m_{\delta j}\|_{\omega_{\lambda}} + \|u^m_i - u^m_j\|_{\omega_{\lambda}} \leq \frac{1}{2}, \lambda.$$
6.3. Final lower bounds. In this subsection we collect the previous efficiency results to complete the proof of Theorem 6.1.

Assuming $h_{NC,T} < 1 \forall T \in T_\delta$, we first look at the result of Proposition 6.6, together with the result of Proposition 6.8. From these we can obtain an efficiency estimate for $\eta_{R,T}$ involving only the exact errors and higher order terms (this is standard; see, for example, [25]). For any given $i \in I$ and a triangle $T \in T_\delta$, we have

$$\eta_{R,T} \lesssim ||h_i - h_{\delta_i}||_T + \sum_{m \in M_T} ||u_i - u_{\delta_i}||_{\frac{1}{2},\ell^T} + h_T ||f_i - f_T||_T$$

$$+ \sum_{m \in M_T} \left(||u_i - u_{\delta_i}||_{\frac{1}{2},\ell^T} + ||h_i - h_{\delta_i}||_T + h_T \eta_{T,R}\right).$$

Then, since $\# M_T \leq \# M_i$ and $\# M_i$ is fixed, thanks to the assumption $h_{NC,T} < 1$ we have

$$\eta_{R,T} \lesssim \frac{1}{1 - h_{NC,T}} \left[||h_i - h_{\delta_i}||_T + \sum_{m \in M_T} ||u_i^m - u_{\delta_i}^m||_{\frac{1}{2},\ell^T} + \left(\sum_{m \in M_T} h_{\ell^T_i}^{\eta_{T,R}}\right)\right]$$

$$+ \frac{h_T}{1 - h_{NC,T}} ||f_i - f_T||_T.$$

Now we consider Proposition 6.8. Since $\# M_T$ is bounded independently on the discretization, summing on all $m \in M_T$ both members we obtain

$$\sum_{m \in M_T} \xi_{NC,T} \lesssim \# M_T ||h_i - h_{\delta_i}||_T + \sum_{m \in M_T} ||u_i^m - u_{\delta_i}^m||_{\frac{1}{2},\ell^T} + \left(\sum_{m \in M_T} h_{\ell^T_i}^{\eta_{T,R}}\right)\eta_{R,T}$$

$$\lesssim ||h_i - h_{\delta_i}||_T + \sum_{m \in M_T} ||u_i^m - u_{\delta_i}^m||_{\frac{1}{2},\ell^T} + h_{NC,T} \eta_{R,T}.$$

We remark that the constants may depend on $\# M_T \leq \# M_i$. We now make use of Proposition 6.6 for bounding $\eta_{R,T}$ with the exact error and $\xi_{NC,T}$, obtaining

$$\sum_{m \in M_T} \xi_{NC,T} \lesssim \left(||h_i - h_{\delta_i}||_T + \sum_{m \in M_T} ||u_i^m - u_{\delta_i}^m||_{\frac{1}{2},\ell^T} + h_{NC,T}\right)$$

$$+ \left(\sum_{m \in M_T} ||u_i - u_{\delta_i}||_{\frac{1}{2},\ell^T} + h_T ||f_i - f_T||_T\right) + h_{NC,T} \sum_{m \in M_T} \xi_{NC,T}.$$

Then

$$\sum_{m \in M_T} \xi_{NC,T}^m \lesssim \frac{1 + h_{NC,T}}{1 - h_{NC,T}} \left(||h_i - h_{\delta_i}||_T \sum_{m \in M_T} ||u_i^m - u_{\delta_i}^m||_{\frac{1}{2},\ell^T}\right)$$

$$+ \frac{h_{NC,T}h_T}{1 - h_{NC,T}} ||f_i - f_T||_T.$$

For any given \( i \in \mathcal{I} \), \( \sigma \in \mathcal{E}_\delta \) and indicating by \( \omega_\sigma \) the set of triangles in \( T_\delta \) having \( \sigma \) as one of their sides, algebraic calculations yield

\[
\xi_{F,\sigma} \lesssim \max \{1, h_\sigma\} \sum_{T \in \omega_\sigma} \frac{1}{1 - h_{NC,T}} \left[ \| h_i - h_\delta \|_T + \sum_{m \in M_T} \| u^m_i - u^m_\delta \|_T \right] + \frac{h_T(1 + h_{NC,T})}{1 - h_{NC,T}} \| f_i - f_T \|_T,
\]

where we see the same kind of dependence. Using the results from Propositions 6.9 and 6.10 and (6.10), (6.11), and (6.12), we can prove Theorem 6.1.

We show here the results of numerical experiments mainly performed in order to evaluate the effectivity index, defined as the ratio between the true error \( err \) and the estimated error \( est_\delta \) (see Table 1):

\[
\varepsilon := \frac{err}{est_\delta}.
\]

In order to approximate the norm of the error \( u - u_\delta \) in the dual space \( H^{-1/2}(\Gamma_m) \) \( \forall m \in M \), we have used the following weighted \( L^2(\Gamma_m) \) norm:

\[
\forall i \in \mathcal{I}, \forall m \in M_i, \| u^m_i - u^m_\delta \|_{1/2, \Gamma_m} \approx \left( \sum_{\lambda \in \Lambda_{m,i}} h_\lambda \| u^m_i - u^m_\delta \|^2_{\Gamma_m} \right)^{1/2},
\]

where \( \Lambda_{m,i} \) is defined as the discretization of the trace \( \Gamma_m \) induced by the mesh \( T_\delta \).
We consider three DFNs, as shown in Figure 2. All simulations are performed using linear finite elements on a sequence of refined grids, and using, for each trace \( \Gamma_m \), a continuous piecewise linear approximation for \( u^m_i \) and \( u^m_j \) on the induced meshes \( \Lambda_{m,i} \) and \( \Lambda_{m,j} \), respectively. In all the considered meshes, traces are arbitrarily placed with respect to the mesh-edges (full nonconformity between the meshes).

All the results are collected in Table 1, where the effectivity index \( \varepsilon \) for the different cases is reported. Further, Figure 3 shows the behavior of the error estimator \( \text{est} \delta \) and of the error \( \text{err} \) with respect to the meshsize for the three DFNs.

7.1. Problem test1. The first test problem deals with two identical fractures intersecting each other orthogonally (see Figure 2a):

\[
\begin{align*}
F_1 &= \{(x, y, z) \in \mathbb{R}^3 : -1 < z < 1, y \in (0, 1), x = 0\}, \\
F_2 &= \{(x, y, z) \in \mathbb{R}^3 : -1 < x < 1, y \in (0, 1), z = 0\}.
\end{align*}
\]

We have \( \mathcal{M} = \{1\} \) and \( \Gamma_1 = \{(x, y, z) \in \mathbb{R}^3 : x = 0, z = 0, y \in (0, 1)\} \), and we set homogeneous Dirichlet boundary conditions on both fractures. For further details regarding this problem, we refer the reader to [7].

Results for this first problem are reported in Table 1a, where the values of the effectivity indices for different meshsizes are shown. We can see that the effectivity
index is almost independent of the meshsize, with values oscillating in a range between 0.2526 and 0.3518 for \( h \) spanning two orders of magnitude. In Figure 3a we plot the true errors and the estimated errors. In the legend of this figure we report the exponent \( m \) of the fitting of these errors with respect to \( h \) (\( err \simeq h^m \) and \( est_\delta \simeq h^m \)). The plots show a good agreement between the error and the estimator.

### 7.2. Problem test2

In the second test problem we consider the two-fracture DFN displayed in Figure 2b. In particular, \( F_1 \) is not intersected completely by \( F_2 \):

\[
\begin{align*}
F_1 &= \{(x, y, z) \in \mathbb{R}^3 : -1 < x < 1, -1 < y < 1, z = 0\}, \\
F_2 &= \{(x, y, z) \in \mathbb{R}^3 : -1 < x < 0, y = 0, -1 < z < 1\}.
\end{align*}
\]

Again, we have \( \mathcal{M} = \{1\} \) and set \( \Gamma_1 = \{(x, y, z) \in \mathbb{R}^3 : y = z = 0, -1 < x < 0\} \), and Dirichlet boundary conditions are set on all the boundaries. In this case we have a less regular solution around the trace tip (see [8, 4]). In Figure 3d we report a computed solution on \( F_1 \). In Table 1b we report the values of the effectivity indices for different meshsizes. We can see that, again, these values are quite stable with respect to the meshsize. In Figure 3b we plot the true errors and the estimated errors and report the slopes \( m \) of the fitting. The plots show a good agreement between the error and the estimator.

### 7.3. Problem 7_fract

The last test problem considers the DFN of 7 fractures intersecting in 11 traces shown in Figure 2c. We set a constant Dirichlet boundary
condition \( h_D = 10 \) on one side of \( F_6 \) and an homogeneous Dirichlet boundary condition on one side of \( F_7 \) (see Figure 2d). The stated problem has a piecewise linear solution on each fracture (see [7]), which could be exactly computed by the FEM method if one had meshes totally conforming to traces. This is not the case for our meshes; thus this is a good test for the behavior of the nonconformity estimators. In Figure 3c we plot the true errors and the estimated errors, and in Table 1c we report the values of the effectivity indices. We note that for the three coarsest meshes the effectivity indices are larger than the values observed for the other meshes. This shows the influence of nonconformity on the efficiency of the estimate: indeed, these meshes feature a nonconformity indicator \( \max_{T \in T_h} h_{NC,T} \approx 0.8571 \), which yields \( C_{NC} \approx 13 \) (Theorem 6.1). With mesh refinement, starting from the fourth coarsest mesh, we have \( \max_{T \in T_h} h_{NC,T} \leq 0.5 \), and the value of \( C_{NC} \) critically drops to values lower than or equal to 3 (see Remark 2) and the effectivity index becomes almost constant.

7.4. Estimators characterization. It is interesting to characterize the estimators with respect to the information they can provide about the distribution of the errors on the domain. With this target we define, \( \forall T \in T_h \), two different indicators:

\[
\eta_{\text{res},T} := \begin{cases} 
\frac{\eta_{R,T} + \frac{1}{2} \sum_{\sigma \in E_{\delta T}} \xi_{F,\sigma} \chi_{\Gamma_m \cap T = 0}}{\eta_{R,T}} & \text{if } \forall m \in M, \quad |\Gamma_m \cap T| = 0, \\
\eta_{R,T} & \text{otherwise,}
\end{cases}
\]

\[
\eta_{\text{tr},T} := \begin{cases} 
\eta_{P,T} + \xi_{P,T} + \xi_{NC,T} + \frac{1}{2} \sum_{\sigma \in E_{\delta T}} \xi_{F,\sigma} & \text{if } \exists m \in M: \quad |\Gamma_m \cap T| \neq 0, \\
\eta_{P,T} + \xi_{P,T} + \xi_{NC,T} & \text{otherwise,}
\end{cases}
\]

where \( E_{\delta T} \) indicates the set of the edges of \( T \). In Figure 4 we see the behavior of these two quantities for problem test2 on \( F_1 \), whose solution is depicted in Figure 3d. The quantity \( \eta_{\text{res},T} \) provides information about the error on each fracture that is related to the finite element approximation of the solution of (3.9) in the interior of the fractures far from the traces. On the other hand, the quantity \( \eta_{\text{tr},T} \) provides information about the nonconformity errors and the violation of matching conditions on the traces. In Figure 4 we plot these two quantities on the elements of two different meshes for \( F_1 \), the coarsest of which is used for the solution shown in Figure 3d. In the top two panels we report \( \eta_{\text{res},T} \) (left) and \( \eta_{\text{tr},T} \) (right) on the coarse mesh; we see that \( \eta_{\text{res},T} \) is larger where the solution displays strong curvatures, i.e., far from the trace and around the trace tip. Instead, as expected, the conformity indicator \( \eta_{\text{tr},T} \) is concentrated around the trace. A similar behavior with different order of magnitude of the estimators is obtained on the finer grid, shown in the bottom panels.

8. Conclusions. In this paper we have derived residual-based “a posteriori” error estimates for the constrained optimization formulation of a simple model for the flow in DFNs. Numerical results have confirmed very weak dependence of the effectivity index on the meshsize, as well as a very good agreement between the estimator and the error distribution, and we have identified a parameter correlating the estimate with the nonconformity of the meshes. The terms of the estimator can be collected in two indicators with a clear meaning: an indicator related to the error inside each fracture, essentially related to the attitude of the finite element space to describe the hydraulic head in each fracture, and a second indicator essentially concerning the lack of continuity of the hydraulic head, the flux mismatch at the traces, and the nonconformity of the meshes of intersecting fractures. The different nature of the estimators makes them useful tools in an adaptive algorithm, and this will be the subject of future investigations.
Behavior of $\eta_{res,T}$ (left) and $\eta_{tr,T}$ with two different meshsizes.
