Abstract

The scope of the present study is focused on the evaluation of the seismic response of bridges isolated by single concave sliding pendulum isolators (FPS) for the different structural properties when the presence of the rigid abutment is considered or neglected (i.e., isolated viaducts). In this way, they have been defined two specific multi-degree-of-freedom (mdof) models to simulate the elastic behavior of the reinforced concrete pier in combination to the infinitely rigid presence of the deck and to the presence of the rigid abutment if considered. Both the numerical models also account for the non-linear velocity-dependent behavior of the FPS bearings. Considering the aleatory uncertainty in the seismic input by means of several natural records with different characteristics, a parametric analysis is developed for several structural properties. The relevant results expressed as the statistics in non-dimensional form with respect to the seismic intensity have permitted to study the differences between the two numerical models in relation to the effectiveness of the seismic isolation.

Keywords: Seismic isolation, Bridge, Friction pendulum isolators, Performance-based engineering, Seismic reliability.

1 INTRODUCTION

Seismically isolated bridges permit to obtain a substantial reduction of the deck acceleration and, as consequence, of the forces transmitted to the pier in comparison to non-isolated bridges as widely demonstrated in many studies focusing with both elastomeric (LRB) and frictional (FPS) isolators [2]-[8]. This topic is in line with the issue of the infrastructure safety [9]-[10]. Tongaonkar and Jangid [11] evaluated the effects of soil-structure interaction on the peak responses of a three-span continuous deck bridge isolated by the elastomeric bearings particularly, showing their influence to assess the bearing displacements at abutment locations. Contextually, friction pendulum system (FPS) devices have been widely used for their capability to provide an isolation period mass independent and to assure high dissipation and re-centering in addition to their longevity and durability properties [12]-[14]. Several experimental and numerical researches have explored the behavior of the FPS devices [15]-[23]. The seismic response of isolated multi-span continuous deck bridges is investigated in [24] confirming the effectiveness of simplified models in relation to the flexibility of the deck and of the piers. In [25]-[26], it was carried out a large parametric analysis demonstrating the influence of the design parameters on the response of a three-dimensional multi-span continuous steel girder bridge model seismically isolated by the FPS isolators. Moreover, other works have been more oriented to develop design approaches for the isolators. In this context, the seismic reliability-based design (SRBD) approach has been proposed and widely discussed in [27]-[34] as a new methodology mainly aim to provide design solutions for seismic devices taking into account the main uncertainties relevant to the problem itself.

The main goal of this work consists in evaluating the influence of the pier-abutment-deck interaction on the seismic response of bridges isolated by single concave sliding pendulum isolators (FPS) mainly comparing the results with those coming from the seismic response of isolated bridges without considering the presence of the rigid reinforced concrete (RC) abutment (i.e., isolated viaducts). With this aim, two different multi-degree-of-freedom (mdof) models representative, respectively, of a single-column bent viaduct [22] and a multi-span continuous deck bridge [7],[13] are defined. Specifically, a six-degree-of-freedom model is used to represent the dynamic behaviour of both the isolated bridge systems. In fact, in both the mdof models, five vibrational modes are considered to describe the elastic behavior of the RC pier and an additional degree of freedom represents the response of the infinitely rigid RC deck isolated by the FPS devices. If considered, the presence of the RC abutment is assumed rigid and so no degree of freedom is related to that. The FPS isolator behavior is described through a widespread velocity-dependent model. In order to obtain a system response independent from the specific seismic source, a non-dimensional formulation of the motion equations proposed in [20] and herein extended and, in addition, a parametric analysis considering several structural properties is performed with the aim to investigate the differences between the two mdof models in relation to the relevant response parameters. The uncertainty in the seismic input is taken into account by means of a set of natural records with different characteristics. Finally, the optimum values of the sliding friction coefficient able to minimize the pier displacements relative to the ground as a function of the structural properties and of the seismic input intensity considering or neglecting the rigid presence of the abutment (i.e., single-column bent viaduct and multi-span continuous deck bridge) have been derived.

2 NON-DIMENSIONAL MOTION EQUATIONS

The motion equations, in terms of drifts between the different degrees of freedom, governing the seismic response when the isolated system refers to a multi-span continuous deck bridge (e.g., three-span continuous deck bridge) [7],[13], and the presence of the rigid RC abutment is considered (Figure 1(b)), subjected to the seismic input along the longitudinal direction, $\ddot{u}_g(t)$, are:

$$\begin{aligned}
 m_d \ddot{u}_d(t) + m_d \ddot{u}_{p5}(t) + m_d \ddot{u}_{p4}(t) + m_d \ddot{u}_{p3}(t) + m_d \ddot{u}_{p2}(t) + m_d \ddot{u}_{p1}(t) + c_d \dot{u}_d(t) + F_p(t) + F_a(t) &= -m_d \ddot{u}_g(t) \\
 m_{p5} \ddot{u}_{p5}(t) + m_{p5} \ddot{u}_{p4}(t) + m_{p5} \ddot{u}_{p3}(t) + m_{p5} \ddot{u}_{p2}(t) + m_{p5} \ddot{u}_{p1}(t) - c_d \dot{u}_d(t) + c_{p5} \dot{u}_{p5}(t) + k_{p5} u_{p5}(t) - F_p(t) &= -m_{p5} \ddot{u}_g(t) \\
 m_{p4} \ddot{u}_{p4}(t) + m_{p4} \ddot{u}_{p3}(t) + m_{p4} \ddot{u}_{p2}(t) + m_{p4} \ddot{u}_{p1}(t) - c_{p5} \dot{u}_{p5}(t) - k_{p5} u_{p5}(t) + c_{p4} \dot{u}_{p4}(t) + k_{p4} u_{p4}(t) &= -m_{p4} \ddot{u}_g(t) \\
 m_{p3} \ddot{u}_{p3}(t) + m_{p3} \ddot{u}_{p2}(t) + m_{p3} \ddot{u}_{p1}(t) - c_{p4} \dot{u}_{p4}(t) - k_{p4} u_{p4}(t) + c_{p3} \dot{u}_{p3}(t) + k_{p3} u_{p3}(t) &= -m_{p3} \ddot{u}_g(t) \\
 m_{p2} \ddot{u}_{p2}(t) + m_{p2} \ddot{u}_{p1}(t) - c_{p3} \dot{u}_{p3}(t) - k_{p3} u_{p3}(t) + c_{p2} \dot{u}_{p2}(t) + k_{p2} u_{p2}(t) &= -m_{p2} \ddot{u}_g(t) \\
 m_{p1} \ddot{u}_{p1}(t) - c_{p2} \dot{u}_{p2}(t) - k_{p2} u_{p2}(t) + c_{p1} \dot{u}_{p1}(t) + k_{p1} u_{p1}(t) &= -m_{p1} \ddot{u}_g(t)
 \end{aligned} \tag{1}$$

where u_d denotes the horizontal displacement of the deck relative to pier, $u_{p1}, u_{p2}, u_{p3}, u_{p4}, u_{p5}$ are the pier displacements relative between two consecutive dof, $m_d, m_{p1}, m_{p2}, m_{p3}, m_{p4}, m_{p5}$ respectively the mass of the deck and of each dof of the pier, $k_{p1}, k_{p2}, k_{p3}, k_{p4}, k_{p5}$ and $c_{p1}, c_{p2}, c_{p3}, c_{p4}, c_{p5}$ respectively the stiffness and inherent viscous damping coefficient of each dof of the pier, c_d the bearing viscous damping factor, t the time instant, the dot differentiation over time.

Figure 1: 6dof model of a bridge isolated by FPS bearings without pier-abutment-deck interaction (i.e., viaduct) (a); 6dof model of a bridge isolated by FPS bearings considering pier-abutment-deck interaction (b); FPS response (c).

The forces related to both the isolator device placed at the pier level $F_p(t)$ and at the abutment level $F_a(t)$ are the following:

$$F_p(t) = \frac{m_d g}{2} \left[\frac{1}{R_p} u_d(t) + \mu_p (\dot{u}_d) \operatorname{sgn}(\dot{u}_d) \right] \tag{2a}$$

$$F_a(t) = \frac{m_d g}{2} \left[\frac{1}{R_a} \left(u_d(t) + \sum_{i=1}^5 u_{pi} \right) + \mu_a \left(\dot{u}_d(t) + \sum_{i=1}^5 \dot{u}_{pi} \right) \operatorname{sgn} \left(\dot{u}_d(t) + \sum_{i=1}^5 \dot{u}_{pi} \right) \right] \quad (2b)$$

where $k_d = W / R = m_d g / R$, g is the gravity constant, R is the radius of curvature of the FPS device, $\mu(\dot{u}_d(t))$ the sliding friction coefficient, which depends on the bearing slip horizontal velocity $\dot{u}_d(t)$ [31], and $\operatorname{sgn}(\cdot)$ denotes the sign function. As reported in [14], the fundamental vibration period of an isolated bridge, $T_d = 2\pi\sqrt{R/g}$, corresponding to the pendulum behaviour component, depends only on the radius of curvature R . According to [16]-[19], the sliding friction coefficient of teflon-steel interfaces can be expressed by the following equation:

$$\mu(\dot{u}_d) = \mu_{\max} - (\mu_{\max} - \mu_{\min}) \cdot \exp(-\alpha |\dot{u}_d|) \quad (3)$$

where μ_{\max} and μ_{\min} represent, respectively, the maximum value of sliding friction coefficient attained at large velocities and the value at zero velocity. In this study, it is considered that $\mu_{\max} = 3\mu_{\min}$ with the exponent α equal to 30 [20].

What is worth underlying is that, differently to the reaction force of the seismic device on the pier, the reaction force as well as the friction coefficient related to the abutment isolator depend on both the horizontal velocity and displacement [31] of the deck with respect to the ground.

By dividing Eq. (1) by the mass deck m_d , the following equation system is obtained:

$$\ddot{u}_d(t) + \ddot{u}_{p5}(t) + \ddot{u}_{p4}(t) + \ddot{u}_{p3}(t) + \ddot{u}_{p2}(t) + \ddot{u}_{p1}(t) + 2\xi_d \omega_d \dot{u}_d(t) + \frac{g}{2} \left[\frac{1}{R_p} u_d(t) + \mu_p(\dot{u}_d) \operatorname{sgn}(\dot{u}_d) \right] + \frac{g}{2} \left[\frac{1}{R_a} \left(u_d(t) + \sum_{i=1}^5 u_{pi} \right) + \mu_a \left(\dot{u}_d(t) + \sum_{i=1}^5 \dot{u}_{pi} \right) \operatorname{sgn} \left(\dot{u}_d(t) + \sum_{i=1}^5 \dot{u}_{pi} \right) \right] = -\ddot{u}_g(t) \quad (4a)$$

$$\lambda_{p5} \left[\ddot{u}_{p5}(t) + \ddot{u}_{p4}(t) + \ddot{u}_{p3}(t) + \ddot{u}_{p2}(t) + \ddot{u}_{p1}(t) \right] - 2\xi_d \omega_d \dot{u}_d(t) + 2\xi_{p5} \omega_{p5} \lambda_{p5} \dot{u}_{p5}(t) + \lambda_{p5} \omega_{p5}^2 u_{p5}(t) - \frac{g}{2} \left[\frac{1}{R_p} u_d(t) + \mu_p(\dot{u}_d) \operatorname{sgn}(\dot{u}_d) \right] = -\lambda_{p5} \ddot{u}_g(t) \quad (4b)$$

$$\lambda_{p4} \left[\ddot{u}_{p4}(t) + \ddot{u}_{p3}(t) + \ddot{u}_{p2}(t) + \ddot{u}_{p1}(t) \right] - 2\xi_{p5} \omega_{p5} \lambda_{p5} \dot{u}_{p5}(t) - \lambda_{p5} \omega_{p5}^2 u_{p5}(t) + 2\xi_{p4} \omega_{p4} \lambda_{p4} \dot{u}_{p4}(t) + \lambda_{p4} \omega_{p4}^2 u_{p4}(t) = -\lambda_{p4} \ddot{u}_g(t) \quad (4c)$$

$$\lambda_{p3} \left[\ddot{u}_{p3}(t) + \ddot{u}_{p2}(t) + \ddot{u}_{p1}(t) \right] - 2\xi_{p4} \omega_{p4} \lambda_{p4} \dot{u}_{p4}(t) - \lambda_{p4} \omega_{p4}^2 u_{p4}(t) + 2\xi_{p3} \omega_{p3} \lambda_{p3} \dot{u}_{p3}(t) + \lambda_{p3} \omega_{p3}^2 u_{p3}(t) = -\lambda_{p3} \ddot{u}_g(t) \quad (4d)$$

$$\lambda_{p2} \left[\ddot{u}_{p2}(t) + \ddot{u}_{p1}(t) \right] - 2\xi_{p3} \omega_{p3} \lambda_{p3} \dot{u}_{p3}(t) - \lambda_{p3} \omega_{p3}^2 u_{p3}(t) + 2\xi_{p2} \omega_{p2} \lambda_{p2} \dot{u}_{p2}(t) + \lambda_{p2} \omega_{p2}^2 u_{p2}(t) = -\lambda_{p2} \ddot{u}_g(t) \quad (4e)$$

$$\lambda_{p1} \ddot{u}_{p1}(t) - 2\xi_{p2} \omega_{p2} \lambda_{p2} \dot{u}_{p2}(t) - \lambda_{p2} \omega_{p2}^2 u_{p2}(t) + 2\xi_{p1} \omega_{p1} \lambda_{p1} \dot{u}_{p1}(t) + \lambda_{p1} \omega_{p1}^2 u_{p1}(t) = -\lambda_{p1} \ddot{u}_g(t) \quad (4f)$$

and the following ratios are introduced:

$$\omega_d = \sqrt{\frac{k_d}{m_d}}, \quad \omega_{pi} = \sqrt{\frac{k_{pi}}{m_{pi}}}, \quad \xi_d = \frac{c_d}{2m_d \omega_d}, \quad \xi_{pi} = \frac{c_{pi}}{2m_{pi} \omega_{pi}}, \quad \lambda_{pi} = \frac{m_{pi}}{m_d} \quad \text{with } i = 1, \dots, 5 \quad (5)$$

The first two terms denote, respectively, the circular frequency of vibration of the isolated deck and of the i -th lumped mass of the pier; ξ_d is the damping factor of the isolated deck,

ξ_{pi} is the damping factor corresponding to the i -th dof in which the pier has been discretized. The last term represents the i -th mass ratio between the i -th lumped mass of the pier and the deck mass.

With the aim to extend the non-dimensionalization approach proposed by [20]-[21], let us introduce the time scale $\tau = t\omega_d$, in which $\omega_d = \sqrt{k_d / m_d}$ is the fundamental circular frequency of the isolated system with infinitely rigid superstructure, and the seismic intensity scale a_0 , so that $\ddot{u}_g(t) = a_0 \ell(\tau)$, where $\ell(\tau)$ is a non-dimensional function of time describing the seismic input time-history, the following non-dimensional equations can be obtained:

$$\begin{aligned} & \ddot{\psi}_d(\tau) + \ddot{\psi}_{p5}(\tau) + \ddot{\psi}_{p4}(\tau) + \ddot{\psi}_{p3}(\tau) + \ddot{\psi}_{p2}(\tau) + \ddot{\psi}_{p1}(\tau) + 2\xi_d \dot{\psi}_d(\tau) + \left[\frac{1}{2} \psi_d(\tau) + \frac{\mu_p(\dot{\psi}_d)g}{2a_0} \text{sgn}(\dot{\psi}_d) \right] + \\ & + \left[\frac{1}{2} \left(\psi_d(\tau) + \sum_{i=1}^5 \psi_{pi}(\tau) \right) + \frac{g}{2a_0} \left(\mu_d \left(\dot{\psi}_d(\tau) + \sum_{i=1}^5 \dot{\psi}_{pi}(\tau) \right) \right) \left(\text{sgn} \left(\dot{\psi}_d(\tau) + \sum_{i=1}^5 \dot{\psi}_{pi}(\tau) \right) \right) \right] = -\ell(\tau) \end{aligned} \quad (6a)$$

$$\begin{aligned} & \lambda_{p5} \left[\ddot{\psi}_{p5}(\tau) + \ddot{\psi}_{p4}(\tau) + \ddot{\psi}_{p3}(\tau) + \ddot{\psi}_{p2}(\tau) + \ddot{\psi}_{p1}(\tau) \right] - 2\xi_{p5} \dot{\psi}_d(\tau) + 2\xi_{p5} \frac{\omega_{p5}^2}{\omega_d} \lambda_{p5} \dot{\psi}_{p5}(\tau) + \\ & + \lambda_{p5} \frac{\omega_{p5}^2}{\omega_d^2} \psi_{p5}(\tau) - \left[\frac{1}{2} \psi_d(\tau) + \frac{\mu_p(\dot{\psi}_d)g}{2a_0} \text{sgn}(\dot{\psi}_d) \right] = -\lambda_{p5} \ell(\tau) \end{aligned} \quad (6b)$$

$$\lambda_{p4} \left[\ddot{\psi}_{p4}(\tau) + \ddot{\psi}_{p3}(\tau) + \ddot{\psi}_{p2}(\tau) + \ddot{\psi}_{p1}(\tau) \right] - 2\xi_{p5} \frac{\omega_{p5}^2}{\omega_d} \lambda_{p5} \dot{\psi}_{p5}(\tau) + 2\xi_{p4} \frac{\omega_{p4}^2}{\omega_d} \lambda_{p4} \dot{\psi}_{p4}(\tau) - \lambda_{p5} \frac{\omega_{p5}^2}{\omega_d^2} \psi_{p5}(\tau) + \lambda_{p4} \frac{\omega_{p4}^2}{\omega_d^2} \psi_{p4}(\tau) = -\lambda_{p4} \ell(\tau) \quad (6c)$$

$$\lambda_{p3} \left[\ddot{\psi}_{p3}(\tau) + \ddot{\psi}_{p2}(\tau) + \ddot{\psi}_{p1}(\tau) \right] - 2\xi_{p4} \frac{\omega_{p4}^2}{\omega_d} \lambda_{p4} \dot{\psi}_{p4}(\tau) + 2\xi_{p3} \frac{\omega_{p3}^2}{\omega_d} \lambda_{p3} \dot{\psi}_{p3}(\tau) - \lambda_{p4} \frac{\omega_{p4}^2}{\omega_d^2} \psi_{p4}(\tau) + \lambda_{p3} \frac{\omega_{p3}^2}{\omega_d^2} \psi_{p3}(\tau) = -\lambda_{p3} \ell(\tau) \quad (6d)$$

$$\lambda_{p2} \left[\ddot{\psi}_{p2}(\tau) + \ddot{\psi}_{p1}(\tau) \right] - 2\xi_{p3} \frac{\omega_{p3}^2}{\omega_d} \lambda_{p3} \dot{\psi}_{p3}(\tau) + 2\xi_{p2} \frac{\omega_{p2}^2}{\omega_d} \lambda_{p2} \dot{\psi}_{p2}(\tau) - \lambda_{p3} \frac{\omega_{p3}^2}{\omega_d^2} \psi_{p3}(\tau) + \lambda_{p2} \frac{\omega_{p2}^2}{\omega_d^2} \psi_{p2}(\tau) = -\lambda_{p2} \ell(\tau) \quad (6e)$$

$$\lambda_{p1} \ddot{\psi}_{p1}(\tau) - 2\xi_{p2} \frac{\omega_{p2}^2}{\omega_d} \lambda_{p2} \dot{\psi}_{p2}(\tau) + 2\xi_{p1} \frac{\omega_{p1}^2}{\omega_d} \lambda_{p1} \dot{\psi}_{p1}(\tau) - \lambda_{p2} \frac{\omega_{p2}^2}{\omega_d^2} \psi_{p2}(\tau) + \lambda_{p1} \frac{\omega_{p1}^2}{\omega_d^2} \psi_{p1}(\tau) = -\lambda_{p1} \ell(\tau) \quad (6f)$$

The non-dimensional parameters $\psi_{u_d} = \frac{u_{d,peak} \omega_d^2}{a_0}$ and $\psi_{u_p} = \frac{u_{p,peak} \omega_d^2}{a_0} = \frac{\left(\sum_{i=1}^5 u_{pi} \right)_{peak} \omega_d^2}{a_0}$ describe the peak dynamic response of the deck and of pier, respectively. Moreover, from Eq.(5), it is possible to observe that the five non-dimensional Π terms [20]-[21],[35]-[36] that control the system non-dimensional response are:

$$\Pi_{\omega_i} = \frac{\omega_{pi}}{\omega_d}, \quad \Pi_{\lambda_{pi}} = \lambda_{pi} = \frac{m_{pi}}{m_d}, \quad \Pi_{\xi_d} = \xi_d, \quad \Pi_{\xi_{pi}} = \xi_{pi} \quad \text{with } i = 1, \dots, 5 \quad (7)$$

in particular, Π_{ω_i} represents the i -th frequency ratio, $\Pi_{\lambda_{pi}}$ is the i -th mass ratio as previously defined, $\Pi_{\xi_{pi}}$ and Π_{ξ_d} are the inherent viscous damping related to the i -th dof of the pier and to the isolator/deck, respectively. Regarding the control parameters of the pier, indeed, the parameters ω_{pi} are related to the fundamental vibration pulsation ω_p (the first vibration mode)

as well as the sum of the mass ratios is related to the overall mass ratio $\Pi_\lambda = \lambda_p = \sum_{i=1}^5 m_{pi} / m_d$ and, finally, all the damping factors are assumed equal to $\Pi_{\xi_p} = \xi_p$.

The normalized friction coefficients for the FPS devices on the pier and on the abutment are the derived, respectively:

$$\Pi_{\mu_p}(\dot{\psi}_d) = \frac{\mu_p(\dot{\psi}_d)g}{a_0}, \quad \Pi_{\mu_a}\left(\dot{\psi}_d + \sum_{i=1}^5 \dot{\psi}_{pi}\right) = \frac{\mu_a\left(\dot{\psi}_d + \sum_{i=1}^5 \dot{\psi}_{pi}\right)g}{a_0} \quad (8)$$

and since these parameters depend on the response through the corresponding velocities, each one is used in its stead as follows [20]:

$$\Pi_{\mu_p}^* = \frac{\mu_{p,\max}g}{a_0}, \quad \Pi_{\mu_a}^* = \frac{\mu_{a,\max}g}{a_0} \quad (9)$$

It is worth underlining that even if the two FPS devices are equal, $\Pi_{\mu_p}^* = \Pi_{\mu_a}^*$, during the dynamic response the terms of Eq.(8) depend on different velocities.

On the other hand, in the case of a single-column bent viaduct (or neglecting the presence of the abutment) [22],[37], the same 6-degree-of-freedom (dof) model presented above, having 5 degrees of freedom for the elastic RC pier and 1 degree of freedom for the rigid RC deck mass equipped with FPS devices is adopted and shown in Figure 1(a).

The main difference in the form of the equation of motion when the abutment is neglected consists in the absence of the term related to the isolator force placed on the abutment and at the beginning of the paragraph indicated as $F_a(t)$.

Note that cracking phenomena [38]-[42] of the RC deck are herein neglected.

3 GROUND MOTIONS AND INTENSITY MEASURE

3.1 Seismic records

In this study, the record-to-record variability is considered using 30 seismic records selected from 19 seismic different events [43]-[45]. Table 1 reports the details of the earthquakes used for the study.

#	Year	Earthquake Name	Recording Name	Station	Vs30 [m/sec]	Source (Fault Type)	M [-]	R [km]	PGA _{max} [g]

3.2 Intensity measure

The intensity scale factor, a_0 , of Eq. (5) is the seismic intensity measure (IM) used in this study coherently with the performance-based earthquake engineering (PBEE) [46],[47]. In this study, the abovementioned term coincides with to the spectral pseudo-acceleration, $S_A(T_d, \xi_d)$, corresponding to the isolated period of the bridge $T_d = 2\pi / \omega_d$ with the damping ratio $\Pi_{\xi_d} = \xi_d$. As also observed in [20]-[22], since the spectral acceleration is related to the spectral displacement $S_A(T_b, \xi_d) = \omega_d^2 S_d(T_d, \xi_d)$, if all the records are normalized with respect to $S_A(T_d, \xi_d)$, the normalized displacement and force of the isolated bridge deck, in the hypothesis of both a rigid substructure (pier) and absence of the sliding friction, are equal to 1 for each record without any record-to-record variability. In the following analysis, the damping ratio ξ_d is set equal to zero [20],[34],[48] and the corresponding IM is hereinafter denoted to as $IM=a_0=S_A(T_d)$.

4 PARAMETRIC STUDY

In the analysis carried out in this study, the effects of higher order modes due to the flexibility of the elastic RC pier together with of the pier-abutment-deck interaction are investigated and the seismic performance of isolated bridges is assessed. This section describes the results of the parametric study carried out on the two systems of Figure 1 to evaluate the performance of bridge isolated with FPS bearings for different structural properties. The first subsection deals with the response parameters relevant to the seismic performance and the second subsection illustrates the parametric study results.

4.1 Non-dimensional response parameters examined

The following response parameters relevant to the seismic performance assessment of isolated bridges are considered: the peak deck displacement relative to the pier for the model of Figure 1(a) as well as the peak deck displacement relative to the pier or to the abutment for the model of Figure 1(b), $u_{d,peak}$, either important for the design of the FPS isolator and of

the seismic joint deck-abutment, the peak pier displacement $u_{p, peak} = (\sum_{i=1}^5 u_{p_i})_{peak}$ (related to the internal forces in the bridge substructure) for the both models. All these relevant response parameters can be defined in non-dimensional form, in line with Eq.s (4) and (6), as follows:

$$\psi_{u_d} = \frac{u_{d, peak} \omega_d^2}{a_0}, \quad \psi_{u_p} = \frac{u_{p, peak} \omega_d^2}{a_0} = \frac{(\sum_{i=1}^5 u_{p_i})_{peak} \omega_d^2}{a_0} \quad (10)$$

Eq.s (4) and (6) are repeatedly and numerically solved in Matlab–Simulink [49] computing a set of samples for each response parameter for the two structural models. As also described in [20],[21],[48],[50], the response parameters are modeled in probabilistic terms [51]-[58]: the generic response parameter D (i.e., the extreme values ψ_{u_d} , ψ_{u_p} of Eq. (10)) can be fitted by a lognormal distribution estimating the sample geometric mean, $GM(D)$, and dispersion, $\beta(D)$, defined, respectively:

$$GM(D) = \sqrt[N]{d_1 \cdot \dots \cdot d_N} \quad (11)$$

$$\beta(D) = \sigma_{\ln}(D) = \sqrt{\frac{(\ln d_1 - \ln[GM(D)])^2 + \dots + (\ln d_N - \ln[GM(D)])^2}{N-1}} \quad (12)$$

in which d_h is the h -th sample realization of D , and N represents the total number of samples (i.e., ground motions): $h=1, \dots, N$. The k th percentile of the response parameter D can be evaluated as:

$$d_k = GM(D) \exp[f(k)\beta(D)] \quad (13)$$

where $f(k)$ is a function that assumes the following values $f(50) = 0$, $f(84) = 1$ and $f(16) = -1$ [59], for the 50th, 16th and 84th percentile, respectively.

4.2 Non-dimensional results

In this section, the results of the parametric study for the two structural configurations developed on the equivalent 6dof systems, for the different structural properties and 30 ground motion records, are illustrated and commented. Specifically, in line with [2],[11],[13],[25],[60], the parameters $\Pi_{\xi_d} = \xi_d$ and $\Pi_{\xi_p} = \xi_p$ are assumed respectively equal to 0% and 5%, the isolation period T_d varies in the range between 2s, 2.5s, 3s, 3.5s and 4s, the elastic RC pier period T_p equal to 0.2s, $\Pi_\lambda = \lambda$ between 0.1, 0.15 and 0.2, Π_μ^* between 0 and 2. The latter one is related to the FPS device on the pier for the model without the abutment and to the FPS isolators, assumed equal, on the pier and on the abutment for the model of Figure 1(b): $\Pi_{\mu_p}^* = \Pi_{\mu_a}^* = \Pi_\mu^*$. For each parameter combination and for the two structural configurations, the differential motion equations (Eq.s (6) and (12)) have been repeatedly and numerically solved adopting the Bogacki-Shampine and Runge-Kutta-Fehlberg integration algorithm available in Matlab-Simulink [49]. After that, for each normalized response parameter, the geometric mean, GM , and the dispersion, β , have been evaluated by means of Eq.s (11) and (12) and are illustrated in Figures 2-3 for the both structural models. Each figure con-

tains different meshes as many as the values of Π_λ : the arrow indicates the increasing values of Π_λ . Note that for the configuration with the pier-abutment-deck interaction (i.e., multi-span continuous deck bridge), the peak normalized deck displacement, showed in Figures 2, has always been the one between the deck and the abutment. This is because of the elastic response of the pier that reduces the relative displacement between the deck and itself.

Figure 2: Normalized deck displacement vs. Π_μ^* and T_d : median value ((a): analysis with only pier; (c): analysis with the pier-abutment-deck interaction) and dispersion ((b): analysis with only pier; (d): analysis with the pier-abutment-deck interaction) for $T_p=0.2s$ and for different values of Π_λ .

In Figures 2, $GM(\psi_{u_d})$ is quite equal to unit for $\Pi_\mu^* = 0$. For $\Pi_\mu^* \neq 0$, $GM(\psi_{u_d})$ increases slightly for increasing T_d because of the period elongation. Obviously, $GM(\psi_{u_d})$ decreases significantly as Π_μ^* increases showing an hyperbolic trend while it is not heavily influenced by Π_λ . The dispersion $\beta(\psi_{u_d})$, for high T_d , increases for increasing values of Π_μ^* , as a result of the reduction of the efficiency of the *IM*. Obviously, in the situation corresponding to $\Pi_\mu^* = 0$, the dispersion is quite zero for all the values of T_d and of Π_λ considered. The mass ratio Π_λ does not affect significantly the response dispersion. Despite the trends of the both statistics are similar for the two configurations, it is possible to observe that the values of $GM(\psi_{u_d})$ are larger in the case of the model without the pier-abutment-deck interaction. On the other hand, higher values of $\beta(\psi_{u_d})$ are achieved for the model with the pier-abutment-deck interaction.

Figure 3: Normalized pier displacement vs. Π_μ^* and T_d : median value ((a): analysis with only pier; (c): analysis with the pier-abutment-deck interaction) and dispersion ((b): analysis with only pier; (d): analysis with the pier-abutment-deck interaction) for $T_p=0.2s$ and for different values of Π_λ .

Figure 3 represents the response statistics of the normalized pier displacement ψ_{u_p} . For the both structural configurations, $GM(\psi_{u_p})$ decreases for higher values of T_d and of Π_λ as well as for decreasing values of T_p ; whereas it first decreases and then increases for increasing values of Π_μ^* , meaning that there is an optimal value of Π_μ^* able to minimize the geometric mean of the pier displacement. This optimal value varies in a range that depends on the values of T_d and Π_λ and on the structural configuration. Note also that for not optimal values of Π_μ^* , $GM(\psi_{u_p})$ is not so high. Conversely, $GM(\psi_{u_p})$ presents higher values for the structural configuration without the pier-abutment-deck interaction (i.e., single-column bent viaduct). The values of the dispersion $\beta(\psi_{u_p})$ are very low for low Π_μ^* values due to the high efficiency of the *IM* used in this work, and reach their peak for values of Π_μ^* close to the optimal ones. The other system parameters have a reduced influence on $\beta(\psi_{u_p})$ compared to the influence of Π_μ^* . Higher values are achieved for the structural configuration with the pier-abutment-deck interaction (i.e., multi-span continuous deck bridge).

5 OPTIMAL VALUES OF THE SLIDING FRICTION COEFFICIENTS

Once the results from the analysis are obtained, for each parameter combination (i.e., Π_λ and T_d) and structural model (i.e., single-column bent viaduct and multi-span continuous deck bridge), the optimal values of the normalized sliding friction coefficient, $\Pi_{\mu, \text{opt}}^*$, that minimize the median (50th percentile) of the normalized pier displacements ψ_{u_p} have been assessed and are reported in Figure 4. Figure 4 reports the variation of $\Pi_{\mu, \text{opt}}^*$ with Π_λ and T_d and in relation to the two structural models (Figure 4a,b). The optimal values of the sliding friction coefficient manifest a slightly increase as T_d decreases, and this is valid for the either the configurations. It is also observed that, especially for high T_d values, $\Pi_{\mu, \text{opt}}^*$ increases by increasing Π_λ in order to dissipate more energy.

Figure 4: Optimal values of normalized friction that minimize the 50th percentile of the normalized pier displacements vs. Π_λ and T_d , for $T_p=0.2\text{s}$; (a) with only pier; (b) with the pier-abutment-deck interaction.

6 CONCLUSIONS

This paper summarizes the seismic performance of bridges and viaducts isolated with single concave friction pendulum system bearings focusing on the influence of the pier-abutment-deck interaction on the seismic response. The analysis carried out aim to define the optimal isolator friction properties taking into account the uncertainty in the seismic input. Adopting the nondimensionalization of the motion equations, a wide parametric analysis considering several structural properties has been conducted by monitoring the response parameters of interest regarding both an isolated bridge where only the pier response is considered and an isolated bridge where the interaction between pier and abutment is taken into account (i.e., single-column bent viaduct and multi-span continuous deck bridge, respectively). The seismic response of these systems is modelled by employing a six-degree-of-freedom system mainly to capture the effects due to the higher modes of the elastic pier.

As far as the deck response is concerned, the geometric mean of the normalized deck displacement tends to slightly increase for increasing isolation period because of the period elongation and it decreases significantly as the normalized friction increases. It presents higher values in the case of the model with only pier (i.e., single-column bent viaduct). The dispersion increases for increasing both isolation period and normalised friction coefficient. It presents higher values in the case of the model with the pier-abutment-deck interaction.

With regards to the pier response, the geometric mean of the normalized displacement decreases for increasing values of isolation period and of mass ratio, whereas it first decreases

and then increases for increasing values of normalized friction. Assuming that, an optimal value of normalized friction coefficient such that the pier displacement is minimized does exist. Regarding the dispersion, higher values are observed for the pier-abutment-deck interaction model.

Finally, the optimal values of the normalized friction coefficient, able to minimize the 50th percentile of the pier response, as a function of the structural properties and for the both structural models, are estimated. Higher optimum friction coefficients are required, when the pier-abutment-deck interaction (i.e., multi-span continuous deck bridge) is taken into account.
