Analysis on Trees with Nondoubling Flow Measures

Matteo Levi[1] · Federico Santagati[1] · Anita Tabacco[1] · Maria Vallarino[1]

Abstract

We consider trees with root at infinity endowed with *flow measures*, which are nondoubling measures of at least exponential growth and which do not satisfy the isoperimetric inequality. In this setting, we develop a Calderón–Zygmund theory and we define BMO and Hardy spaces, proving a number of desired results extending the corresponding theory as known in more classical settings.

1 Introduction

Let $T = (V, E)$ be a tree, where V is the set of vertices and E the set of edges. We do not put any a priori restriction on the combinatorics of the tree, in particular we do not require T to be homogeneous. We fix an origin $o \in V$, a geodesic g emanating from o and the corresponding point ζ_g in the natural boundary ∂T of the tree. This boundary point serves as a root of T, and induces a level structure on the tree. In this paper we consider *flow measures* on the set of vertices V, i.e., functions $m : V \rightarrow \mathbb{R}^+$ whose value at each point can be reconstructed as the sum of the values the function takes at the *sons* of that point. See Section 2 for all the details.

The interest in such measures comes from the fact that there is a natural injective lifting procedure to map Borel measures on the boundary of the tree to measures on its vertices, and flow measures are exactly the range of such a lifting operator. Moreover, $p-$harmonic functions on trees can be characterized as appropriate potentials of flow measures (see [8]). The word flow is commonly used in Network Theory as such measures are well suited to model physical phenomena such as the circulation of traffic in the cities, of current in electrical circuits, of water in pipes et cetera. The conservation property characterizing flows is equivalent to the *Kirchhoff's current law*: the total current received by a vertex must equal the total current leaving the vertex. The existence of (finite energy) flows on a graph has been proved to have outstanding theoretical importance, being intimately related to the transience and recurrence properties of the graph itself; for a thorough account on this perspective we refer to the beautiful book [17].

The metric measure space (T, d, m), where T is a general infinite tree, d the geodesic distance and m a flow measure, is a concrete example of nondoubling metric space without growth restrictions on the measure. Our goal is to investigate some pieces of theory coming from classical Harmonic Analysis in this context; in particular, we study the behaviour of a Hardy-Littlewood maximal function, we describe a Calderón–Zygmund decomposition of integrable functions and we introduce Hardy and BMO spaces on (T, d, m), when m is locally doubling.

The classical Calderón–Zygmund theory and the standard theory of Hardy and BMO spaces [9, 11, 23] were introduced in $(\mathbb{R}^n, d, \lambda)$, where d is the Euclidean metric and λ denotes the Lebesgue measure and more generally on spaces of homogeneous type, namely metric measure spaces (X, d, μ) where the doubling condition is satisfied, i.e., there exists a constant C such that

$$\mu\big(B_{2r}(x)\big) \le C\,\mu\big(B_r(x)\big) \qquad \forall x \in X, \quad \forall r > 0, \tag{1}$$

where $B_r(x)$ denotes the ball centred at x of radius r.

It is worth noticing that in the setting of (possibly weighted) graphs with the doubling property new Hardy and BMO spaces associated with a discrete Laplacian were introduced in [4, 5, 12]; various characterizations of such spaces and applications to singular integrals were obtained.

Extensions of the theory of singular integrals and of the Hardy and BMO spaces have been considered also on various metric measure spaces not satisfying the doubling condition Eq. 1 but fulfilling some other measure growth assumption (see, e.g., [6, 18, 20, 22, 24–27]) or a geometric condition (see [19]). We remark that the locally doubling flow measures we consider can grow at arbitrarily large rate.

Carbonaro, Mauceri and Meda [6] defined a Hardy space adapted to any metric measure space which satisfies some geometric assumption, namely the local doubling property, the isoperimetric property and the approximate midpoint property. Their theory does not apply to the spaces we consider since they do not satisfy the isoperimetric property.

We also mention that some results on homogeneous trees endowed with the counting measure, which is not a flow measure, have been obtained in the literature. More precisely, Naor and Tao [21] studied the boundedness of the Hardy–Littlewood maximal function with respect to the family of balls. The boundedness of singular integrals associated with the combinatorial Laplacian has been investigated in [10], while Celotto and Meda [7] studied various Hardy spaces in this context. In [16] the authors introduced Hardy spaces of harmonic functions on nonhomogeneous trees; their theory can be thought as an analog of the classical theory of Hardy spaces on the unit disc.

This paper generalizes in various directions the results in [1, 14] and [2] concerning a Calderón–Zygmund theory, Hardy and BMO spaces on homogeneous trees endowed with a distinguished measure. First of all, we consider general non-regular trees. Moreover, we consider a class of measures, i.e., the locally doubling flows, among which the measure considered in [1, 2, 14] is a particular example. The definition of the family of admissible sets, which is a key ingredient to develop all the theory of the present paper, is strongly inspired by the one given by Hebisch and Steger in [14], but is more general, even in their setting. Indeed, the shape of our sets is less rigid and this allows to obtain suitable decomposition and expansion algorithms which were not available in the setting of [14]. These algorithms are also a fundamental tool to prove some results involving Hardy and BMO spaces which were missing in [1, 2].

The paper is organized as follows. In Section 2 we introduce the notation and characterize the properties of being locally doubling, doubling and of exponential growth for flow measures. Moreover, we show that these measures never satisfy the isoperimetric property. We then restrict our attention to a tree T endowed with a locally doubling flow measure m; this implies that T is of uniformly bounded degree. In such a case, we introduce a family of subsets of V called *admissible trapezoids* (Section 3), which exhibits interesting geometric properties. In particular, the Hardy–Littlewood maximal operator associated with such a family turns out to be of weak type $(1, 1)$ and bounded on $L^p(m)$ for every $p \in (1, \infty]$. Moreover, we show that every integrable function admits a Calderón–Zygmund decomposition where the admissible trapezoids are involved. In Section 4 we introduce a Hardy space $H^1(m)$ and a space $BMO(m)$ related with the family of admissible trapezoids; we prove that $BMO(m)$ can be identified with the dual of $H^1(m)$ and that a John–Nirenberg inequality holds in this setting. Finally, in Section 5, we show that such spaces satisfy good interpolation properties, both with respect to the real and the complex interpolation methods, so that they can be used for endpoint boundedness results for integral operators. Applications of this theory to the study of boundedness of integral operators, like Riesz transforms and spectral multipliers of suitable Laplacians, is work in progress.

Along the paper, constants appearing in different inequalities are sometimes related to each others. To highlight such connections we prefer to provide explicitly most of the constants. However, when the exact values are unimportant for us, we use the standard notation $A(x) \lesssim B(x)$ to indicate that there exists a positive constant c, independent from the variable x but possibly depending on some involved parameters, such that $A(x) \leq cB(x)$ for every x.

2 Preliminaries

2.1 Trees with Root at Infinity

An unoriented graph is a vertex set V endowed with a symmetric relation $\sim$. If $x \sim y$ we say there is an edge connecting x to y, which we identify with the one connecting y to x. The set of edges is denoted by E. Let $q(x) = |\{y \in V : y \sim x\}| - 1$ denote the number of neighbours of x (minus 1, for convenience of notation). We say that the graph is of *bounded degree* if there exists a universal positive constant q such that $q(x) \leq q$ for all $x \in V$. Consider a sequence of vertices $\{x_j\}$ such that $x_j \sim x_{j+1}$. This naturally identifies an associated sequence of edges $\{e_j\}$, where e_j is the edge connecting x_j to x_{j+1}. We say that $\{x_j\}$ is a *path* if $\{e_j\}$ does not contain repeated edges. If the path $\gamma = \{x_j\}_{j=0}^n$ is finite, x_0 and x_n are called the endpoints of γ. The geodesic distance $d(x, y)$ counts the minimum

number of edges one has to cross while moving from x to y along a path. Any path realizing such a distance for every couple of vertices belonging to it is called a geodesic. We denote by Γ the family of geodesics.

A graph is connected if every couple of vertices belongs to a path. Connected graphs having no paths with repeated vertices are called trees. In particular the relation $\sim$ is never transitive on a tree - there are no triangles. Also, it is clear that trees are uniquely geodesic spaces: for every couple of vertices x, y in a tree T, there exists a unique path (which is necessarily a geodesic) having x and y as endpoints. Hence, without risk of confusion, we also denote by $[x, y]$ such a geodesic.

Let $T = (V, E)$ be a tree. We fix a distinguished point $o \in V$ which we call the *origin* of the tree. We write Γ_0 for the family of half infinite geodesics having an endpoint in the origin, $\Gamma_0 = \{\gamma = \{x_j\}_{j=0}^{\infty} \in \Gamma, x_0 = o\}$. The *boundary* of the tree ∂T is classically identified with the set of labels corresponding to elements of Γ_0,

$$\partial T = \{\zeta_\gamma : \gamma \in \Gamma_0\}.$$

A point $z \in \overline{V} = V \cup \partial T$ can be chosen to play the role of *root* of the tree. The role of such a point is to induce a partial order relation on $\overline{V}$, or more intuitively, to act as a base point for a radial foliation of the tree. We say that $x \geq y$ if and only if $x \in [z, y]$. We define the projection of x on the geodesic $[o, z]$ as

$$\Pi_z(x) = \arg \min_{y \in [o,z]} d(x, y),$$

and the *level* of x as

$$\ell(x) = d(o, \Pi_z(x)) - d(\Pi_z(x), x).$$

In levels notation the rule for the order relation says that $x \geq y$ if and only if $\ell(x) - \ell(y) = d(x, y)$. Observe that if $x \leq o$, then $\ell(x) = -d(x, o)$. In particular, if one chooses the root to coincide with the origin, then the level of a point is just (minus) its distance from the origin, i.e., its radial coordinate, and the tree can be interpreted as a model for the unit disc $\mathbb{D}$. In this paper, however, we decide to fix the root as a point $\zeta_g \in \partial T$, g being a distinguished half infinite geodesic starting at the origin. With this choice, the geometric interpretation of a level set in the unit disc is not so neat anymore. Instead, it is helpful to switch to a half-plane model point of view; in analogy to the conformal trasformation of the unit disc onto the upper-half plane, mapping $\partial \mathbb{D} \setminus \{\zeta\}$ to $\mathbb{R}$ and ζ to the point at infinity, we can interpret the tree rooted at ζ_g as a conformal copy of the one rooted at the origin, and its boundary as a representation of the Riemann sphere. Following this point of view, hereinafter we will write ∂T for $\{\zeta_\gamma \in \Gamma_0 \setminus \{\zeta_g\}\}$ and interpret ζ_g as a separate special point (the point at infinity). It is easily seen that, with the upper-half plane model in mind, a level set plays the role of a line parallel to the real axis, which in the disc model would be an horocycle tangent to the boundary point ζ_g, and the level of a point plays the role of y-coordinate in the parametrization of the tree.

We define some further notation that will be useful in the treatment. The *predecessor* of x is the unique vertex $p(x)$ such that $x \sim p(x)$ and $\ell(p(x)) = \ell(x) + 1$, while y is a *son* of x if it belongs to the set $s(x) = \{y \sim x : \ell(y) = \ell(x) - 1\}$. Observe that $|s(x)| = q(x)$. We define the *confluent* of $x, y \in \overline{V}$ to be the point

$$x \wedge y = \arg \max\{\ell(z) : z \in [x, y]\} = \arg \min\{\ell(z) : z \geq x, z \geq y\}.$$

Observe that the level function can be written as $\ell(x) = d(x \wedge o, o) - d(x \wedge o, x)$. The *tent* rooted in x is the set $V_x = \{y \in V : y \leq x\}$ and we denote by ∂T_x its boundary, $\partial T_x = \{\zeta \in \partial T : \zeta \leq x\} = \{\zeta \in \partial T : \zeta \wedge x = x\}$. The family $\{\partial T_x\}_{x \in V}$ can be used

as a basis for the topology on ∂T. Borel measures on the boundary can then be considered, accordingly.

Finally, we introduce the following convenient notation which will be widely used throughout the paper: whenever we fix a vertex x_0, we denote by x_k its $k-$th predecessor, namely $x_k = p(x_{k-1})$ for any integer $k \geq 1$. Clearly $x_k = x_k(x_0)$ depends on x_0, but since the basis point x_0 will always be clear from the context we will simply write x_k.

2.2 Flow Measures

From now on, T will always denote a tree rooted at ζ_g, endowed with the level structure described in the previous section, and V the set of its vertices. Since V is a discrete set, every function on V defines a measure. With some abuse of notation, given a function $m : V \to \mathbb{R}$ we denote by m also the associated measure, given by

$$m(A) = \sum_{x \in A} m(x), \quad A \subseteq V.$$

Given a function $f : V \to \mathbb{C}$ and a set $A \subset V$, we define $\int_A f \, dm = \sum_{y \in A} f(y)m(y)$. We say that m is a *flow* if, $\forall x \in V$, it holds

$$m(x) = \sum_{y \in s(x)} m(y).$$

Flow measures on V are special in the fact that they are in a 1-1 relation with Borel measures on the boundary of the tree. More precisely, any flow measure m can be extended to a measure on ∂T through the correspondence

$$m(\partial T_x) = m(x), \tag{2}$$

and conversely, if m is a non-negative Borel measure on ∂T, then the function $m : V \to \mathbb{R}$ defined by Eq. 2 is a flow (by the additivity property of measures). Observe that, if a non-negative flow vanishes at a point x, then it vanishes on the whole tent V_x. Throughout the paper, flow measures will be implicitly assumed to be strictly positive.

We are interested in the relation between flow measures and the doubling property. Let $S_r(x_0) = \{x \in V : d(x, x_0) = r\}$ and $B_r(x_0) = \{x \in V : d(x, x_0) \leq r\}$ be, respectively, the sphere and the ball of radius $r \in \mathbb{N}$ centered at $x_0 \in V$ with respect to the geodesic distance metric. We say that m is a *locally doubling measure* on V if, for every $r > 0$, there exists a constant $C_r > 1$ such that

$$m(B_{2r}(x_0)) \leq C_r m(B_r(x_0)), \quad \forall x_0 \in V. \tag{3}$$

If there exists a universal constant $C > 1$ such that for every $r > 0$, relation Eq. 3 holds with $C_r = C$, then the measure m is said (globally) *doubling*.

Next technical lemma provides explicit expressions for the mass of spheres and balls for a general flow measure and useful upper and lower bounds for the ratio between measures of balls.

Lemma 2.1 *Let m be a flow measure. Fix $x_0 \in V$ and, for $k \geq 0$, let $x_{k+1} = p(x_k)$. For every $r \in \mathbb{N}$, it holds*

(i) $m(S_r(x_0)) = m(x_{r-1}) + m(x_r)$;

(ii) $m(B_r(x_0)) = 2 \sum_{j=0}^{r-1} m(x_j) + m(x_r)$;

(iii) $\frac{m(x_{2r})}{(2r+1)m(x_r)} \leq \frac{m(B_{2r}(x_0))}{m(B_r(x_0))} \leq \frac{(4r+1)m(x_{2r})}{m(x_r)}$.

Proof Define the $l-$level slice of the sphere $S_r(x_0)$ as $S_r^l(x_0) = S_r(x_0) \cap \{x \in V : \ell(x) = l\}$, and set $l(k) = \ell(x_0) - r + 2k$. Then

$$S_r(x_0) = \bigcup_{k=0}^{r} S_r^{l(k)}(x_0).$$

It's easily seen that

$$S_r^{l(0)}(x_0) = \{x \in V : x \leq x_0, \ell(x) = l(0)\},$$
$$S_r^{l(k)}(x_0) = \{x \in V : x \leq x_k, \ell(x) = l(k)\} \setminus \{x \in V : x \leq x_{k-1}\}, \qquad \text{for } k > 1.$$

Observe that $m(S_r^{l(0)}(x_0)) = m(x_0)$, $S_r^{l(r)}(x_0) = \{x_r\}$ and, for $1 \leq k \leq r-1$, $S_r^{l(k)}(x_0) \neq \emptyset$ if and only if $q(x_k) \geq 2$. If m is a flow measure, then

$$m(S_r^{l(k)}(x_0)) = m(s(x_k)) - m(s(x_{k-1})) = m(x_k) - m(x_{k-1}), \quad 1 \leq k \leq r-1,$$

which equals zero if $q(x_k) = 1$, as expected. The flow measure of the sphere, for $r \geq 1$, is then given by

$$m(S_r(x_0)) = \sum_{k=0}^{r} m(S_r^{l(k)}(x_0)) = m(x_0) + m(x_r) + \sum_{k=1}^{r-1} m(x_k) - m(x_{k-1}) = m(x_{r-1}) + m(x_r). \tag{4}$$

We can now derive the flow measure of the ball considering its foliation by means of spheres,

$$m(B_r(x_0)) = \sum_{j=0}^{r} m(S_j(x_0)) = m(x_0) + \sum_{j=1}^{r} m(x_{j-1}) + m(x_j) = 2 \sum_{j=0}^{r-1} m(x_j) + m(x_r). \tag{5}$$

Clearly $m(B_r(x_0)) \geq \sum_{j=0}^{r} m(x_j)$, and we derive

$$\frac{m(x_{2r})}{(2r+1)m(x_r)} \leq \frac{\sum_{j=0}^{2r} m(x_j)}{2 \sum_{j=0}^{r-1} m(x_j) + m(x_r)} \leq \frac{m(B_{2r}(x_0))}{m(B_r(x_0))} \leq \frac{2 \sum_{j=0}^{2r-1} m(x_j) + m(x_{2r})}{\sum_{j=0}^{r} m(x_j)} \leq \frac{(4r+1)m(x_{2r})}{m(x_r)}.$$

$\square$

Next proposition gives two properties which are equivalent to the locally doubling condition and more convenient to use in practice.

Proposition 2.2 *Let m be a flow measure. The following are equivalent.*

(i)   *The measure m is locally doubling.*
(ii) *There exists a constant $c > 1$ such that*

$$m(x) \leq cm(y), \qquad \forall x \in V, y \in s(x), \tag{6}$$
$$m(x) \geq \frac{c}{c-1} m(y), \qquad \forall x \in V \text{ with } q(x) \geq 2, y \in s(x). \tag{7}$$

Proof Assume Eq. 6 holds. Then for any $x_0 \in V, r > 0$, from Lemma 2.1 we have

$$\frac{m(B_{2r}(x_0))}{m(B_r(x_0))} \leq (4r+1)c^r = C_r,$$

hence m is locally doubling.

Conversely, let m be a locally doubling flow. Then, for every $x \in V$, $y \in s(x)$ and $z \in s(y)$, again from Eq. 3 and Lemma 2.1,

$$C_1 \geq \frac{m(B_2(z))}{m(B_1(z))} \geq \frac{m(x)}{3m(y)}. \tag{8}$$

If Eq. 6 would not hold, we could find two sequences of vertices $\{x_j\}$ and $\{y_j\}$, with $y_j \in s(x_j)$, such that $\limsup_j m(x_j)/m(y_j) = +\infty$, contradicting Eq. 8. Moreover, inequality Eq. 6 implies that

$$m(x) = \sum_{y \in s(x)} m(y) \geq \frac{1}{c} \sum_{y \in s(x)} m(x) = \frac{q(x)m(x)}{c}.$$

Hence, $q(x) \leq c$ for all $x \in V$. Then, for $x \in V$ with $q(x) \geq 2$ we have

$$m(x) = m(y) + \sum_{z \in s(x) \setminus \{y\}} m(z) \geq m(y) + \frac{q(x) - 1}{c} m(x),$$

from which it follows that

$$m(x) \geq \frac{c}{c - q(x) + 1} m(y) \geq \frac{c}{c - 1} m(y).$$

This completes the proof. $\qquad\qquad\square$

In the previous argument it is proved between the lines a fact which is itself important and deserves some attention. We restate it here as a corollary.

Corollary 2.3 *If T admits a locally doubling flow measure, then*

$$q(x) \leq c, \quad \forall x \in V,$$

with the same constant c as in Eq. 6.

Observe that the opposite is not true, i.e., not every flow on a tree of bounded degree is locally doubling. In fact, it is clear that any measure m with a super exponential growth along the geodesic g, so not satisfying Eq. 6, can be defined outside g in such a way to be a flow.

Remark 2.4 Note that unless $T = \mathbb{Z}$, namely the trivial tree where each vertex has exactly two neighborhoods (a predecessor and a son), in fact the constant c in Eq. 6 must be greater or equal than 2, as a consequence of Corollary 2.3.

Remarkably, it turns out that trees with root at infinity do not admit doubling flow measures, unless almost all of their vertices have only one son. Let $n : \Gamma \to \mathbb{N}$ be the function counting the number of vertices having at least two sons along each geodesic,

$$n(\gamma) = |\{y \in \gamma : q(y) \geq 2\}|.$$

We have the following characterization.

Theorem 2.5 *A tree T rooted at infinity admits a doubling flow measure if and only if it has uniformly bounded degree and*

$$\sup_{\gamma \in \Gamma} n(\gamma) = M < \infty. \tag{9}$$

Observe that it is enough to take the supremum in Eq. 9 over doubly infinite geodesics having one of the endpoints in ζ_g: in fact, if $\zeta, \eta \in \partial T \setminus \{\zeta_g\}$, then clearly $n([\zeta, \eta]) \leq n([\zeta, \zeta_g]) + n([\eta, \zeta_g])$. The above theorem is an immediate consequence of the following proposition, which characterizes trees on which the locally doubling condition implies the doubling condition for flows.

Proposition 2.6 *A locally doubling flow measure on T is doubling if and only if* Eq. 9 *holds.*

Proof Let Eq. 9 hold, m be a locally doubling flow and c be the constant in Eq. 6. Then for every $x_0 \in V, r \geq 2$, it holds

$$\frac{m(B_{2r}(x_0))}{m(B_r(x_0))} \leq \frac{(4r+1)m(x_{2r})}{(r-1)m(x_{\lceil r/2 \rceil})} \leq \frac{(4r+1)c^M m(x_{\lceil r/2 \rceil})}{(r-1)m(x_{\lceil r/2 \rceil})} \leq 9c^M.$$

If $r = 1$, we easily get the uniform boundedness of $\frac{m(B_2(x_0))}{m(B_1(x_0))}$ by the definition of locally doubling measure. Hence, m is doubling.

Conversely, let m be a doubling flow, C the doubling constant and $x, z \in V$ with $z > x$. Choose $x_0 < x$ such that $r = d(x_0, x) = 2d(x, z)$. Then,

$$C \geq \frac{m(B_{2r}(x_0))}{m(B_r(x_0))} \geq \frac{2\sum_{j=3r/2}^{2r-1} m(x_j)}{(2r-1)m(x)} \geq \frac{rm(z)}{(2r-1)m(x)}.$$

Hence, $m(z) \leq 3Cm(x)$. On the other hand, m is locally doubling, so by Eq. 7 $m(z) \geq k^{n([p(x),z])}m(x)$. Then, $n([p(x), z]) \leq \log_k(3C)$. By the generality of x and z the result follows. $\square$

Proof of Theorem 2.5 Clearly if T admits a doubling measure then it must have bounded degree by Corollary 2.3 and satisfies Eq. 9 by Proposition 2.6. Conversely, let T be a tree satisfying Eq. 9 and suppose that $q(x) \leq c$ for every $x \in V$. Then any measure m satisfying $m(p(x)) = q(p(x))m(x)$ at every vertex x is a locally doubling flow since $m(p(x)) \leq cm(x)$. We conclude by Proposition 2.6. $\square$

Definition 2.7 We say that m has at least exponential growth if, for all $x_0 \in V$, there exist $r_0 = r_0(x_0) \in \mathbb{N}$, $\beta = \beta(x_0) > 0$ and $\alpha = \alpha(x_0) > 0$ such that $m(B_r(x_0)) \geq \beta e^{\alpha r}$ for all $r > r_0$.

Proposition 2.8 *Let m be a locally doubling flow. Then m has at least exponential growth if and only if for all $x_0 \in V$ there exist $r_0 = r_0(x_0) \in \mathbb{N}$ and $\alpha = \alpha(x_0) > 0$ such that $n([x_1, x_r]) \geq \alpha r$ for all $r > r_0$.*

Proof For the sufficient condition, by Eq. 7 we have that for any $x_0 \in V$ and $r \geq r_0$

$$m(B_r(x_0)) \geq m(x_r) \geq m(x_0)k^{n([x_1, x_r])} \geq m(x_0)k^{\alpha r} \geq \beta e^{\alpha r}.$$

Conversely, assume that m has at least exponential growth. Then for some α, β, r_0 and all $r > r_0$ we have

$$\beta e^{\alpha r} \leq m(B_r(x_0)) \leq (2r+1)c^{n([x_1, x_r])}m(x_0),$$

where c is the constant in Eq. 6. Then we get

$$c^{n([x_1, x_r])/r} \geq e^{\alpha} \Big(\frac{\beta}{(2r+1)m(x_0)} \Big)^{1/r} \longrightarrow e^{\alpha} > 1 \quad \text{as } r \to \infty.$$

The assumption that there exists an $x_0 \in V$ such that $\liminf_{r \to \infty} n([x_1, x_r])/r = 0$ would then lead to a contraddiction. $\qquad \square$

We end the section by observing that the *isoperimetric inequality* does not hold for flow measures on T. We say that a measure m satisfies the isoperimetric inequality on T if there exists a constant $C_{iso} > 0$ such that for every bounded $A \subset V$

$$m(\partial A) \geq C_{iso} m(A),$$

where the boundary of A is defined as $\partial A = \{x \in A \ : \ \exists \ y \in A^c \text{ such that } y \sim x\}$. Now, given a ball $B = B_r(x_0)$, $r > 0$ and $x_0 \in V$, set $B^+ = B \cap \{x \in V \ : \ x > x_0\}$, $B^- = B \cap \{x \in V \ : \ x \leq x_0\}$. Note that $B^+ \cup B^- \subset B$, with equality holding if and only if $r \leq 1$.
A flow measure does not satisfy the isoperimetric inequality. Indeed,

$$\frac{m(\partial B^-)}{m(B^-)} = \frac{2m(x_0)}{(r+1)m(x_0)} = \frac{2}{r+1} \to 0 \quad \text{as } r \to +\infty.$$

3 Calderón–Zygmund Theory

The classical Calderón-Zygmund theory heavily relies on the fact that metric balls enjoy the doubling property with respect to the given measure. As shown in the previous section, flow measures on the tree tested on balls are typically non-doubling. For this reason, inspired by the seminal work [14], we substitute balls with a different family of sets which will show to be doubling in an appropriate sense, and can be used as base sets for building up a Calderón-Zygmund theory in this contest.

3.1 Admissible Trapezoids

For $h'' > h' \in \mathbb{N} \setminus \{0\}$, we define the *trapezoid* rooted at $x_0 \in V$ of parameters h', h'' as

$$R = R_{h'}^{h''}(x_0) = B_{h''-1}^-(x_0) \backslash B_{h'-1}^-(x_0) = \{x \in V \ : \ x \leq x_0, \ \ell(x_0)-h'' < \ell(x) \leq \ell(x_0)-h'\}.$$

Observe that if m is a flow measure, then

$$m(R) = m(x_0)(h'' - h'),$$

reason why we call the quantity $h(R) = h'' - h'$ the *height* of the trapezoid.

Singletons $\{x_0\}$ are also considered to be trapezoids. Given a number $\beta \geq 12$ [1] we say that a trapezoid R is admissible (with respect to β) if either $R = \{x_0\}$ or $R = R_{h'}^{h''}(x_0)$ with $2 \leq h''/h' \leq \beta$, for some $x_0 \in V$. We fix β once for all and we denote by $\mathcal{R}$ the corresponding family of admissible trapezoids.

Assumptions From now on we will assume that T is a tree rooted at $\zeta_g \in \partial T$, V is its set of vertices, and

---

[1]This specific lower bound on β is needed to guarantee enough room to perform the expansion algorithm described below.

(1) $m : V \to \mathbb{R}^+$ is a locally doubling flow measure;
(2) T is of uniformly bounded degree, i.e., $q(x) \le c, \forall x \in V$.

By Corollary 2.3 (2) is a consequence of (1), but we explicitly state it here to recall once for all the notation of the constant c.

3.2 Decomposition and Expansion Algorithms

We now describe procedures to define dyadic decompositions and expansions of admissible trapezoids. Let $R = R_{h'}^{h''}(x_0) \in \mathcal{R}$, and set $\gamma = h''/h'$. We have the following *decomposition algorithm*:

- if $R = \{x_0\}$, return R;
- if $h' = 1$ and $h'' = 2$, cut R in the disjoint union of its vertices: they are at most c, all brothers, sons of x;
- if $h' = 1$ and $h'' = 3$ or $\gamma \ge 4$, cut R horizontally producing

$$R_u = R_{h'}^{2h'}(x_0), \quad R_d = R_{2h'}^{h''}(x_0);$$

- else, cut R vertically producing,

$$R_y = R_{h'-1}^{h''-1}(y), \quad y \in s(x_0).$$

It is easy to see that in any case the produced sub-trapezoids are admissible. Let $\mathcal{F}(R, 1)$ be the output of the algorithm, which is a family of at most c trapezoids forming a partition of R, and for $k \ge 1$ let $\mathcal{F}(R, k + 1)$ be the family of trapezoids produced by applying the decomposition algorithm to each element of $\mathcal{F}(R, k)$. Observe that the algorithm can be iterated until one reaches the trivial partition of the given trapezoid R, which is the one constituted of singletons only.

Conversely, if we want to produce the dyadic father of the given admissible trapezoid R, we proceed via the following *expansion algorithm*:

- if $R = \{x_0\}$, we expand it to $R' = s(p(x_0))$
- if $h' = 1$ and $h'' = 2$, we expand R to $R' = R_1^3(p(x_0))$
- if $\gamma \ge 3$, we expand R horizontally to $R' = R_{h'+1}^{h''+1}(p(x_0))$
- else, we can decide whether to expand R down vertically to $R' = R_{h'}^{2h''}(x_0)$ or up vertically to $R' = R_{\lfloor h'/2 \rfloor}^{h''}(x_0)$.

Observe that no vertical expansion is performed as far as $h' = 1$, so that also the up-vertical expansion is always properly defined. It is easy to check that any of the above expansion steps produces a new admissible trapezoid R' which contains R. The following property can be considered as a substitute for the doubling property in the proposed contest.

Proposition 3.1 *Let $R \in \mathcal{R}$, R' its expansion and $Q \in \mathcal{F}(R, 1)$. Then,*

$$\frac{1}{\widetilde{C}} m(R') \le m(R) \le \widetilde{C} m(Q),$$

where $\widetilde{C} = \max\{2c, \beta - 1, 3\}$.

Proof Let $R = R_{h'}^{h''}(x_0)$ be an admissible trapezoid, $Q \in \mathcal{F}(R, 1)$ and R' the dyadic expansion of R. The following estimates hold:

$$m(R) \leq \begin{cases} m(Q), & \text{if } R = \{x_0\} \\ (\beta - 1)m(Q) & \text{if } Q = R_u \\ 3m(Q)/2, & \text{if } Q = R_d \\ cm(Q), & \text{otherwise,} \end{cases}$$

$$m(R') \leq \begin{cases} cm(R), & \text{if } R = \{x_0\} \text{ or } \gamma \geq 3 \\ 2cm(R), & \text{if } h' = 1, h'' = 2 \\ 3m(R), & \text{if } R' \text{ is down vertical expansion of } R \\ 5m(R)/2 & \text{if } R' \text{ is up vertical expansion of } R. \end{cases}$$

$\square$

3.3 Hardy–Littlewood Maximal Function

In this section we prove the L^p boundedness of the Hardy–Littlewood maximal function associated to the family $\mathcal{R}$ when $p \in (1, +\infty]$ and we also show that M is of the weak-type (1,1). Given a function $f : V \to \mathbb{C}$, its maximal function is defined by

$$Mf(x) = \sup_{R \ni x} \frac{1}{m(R)} \int_R |f| \, dm,$$

where the supremum is taken over all $R \in \mathcal{R}$ such that $x \in R$.
Given $R = R_{h'}^{h''}(x) \in \mathcal{R}$ we define its *envelope* as

$$\tilde{R} = R_{\lceil \frac{h'}{\beta} \rceil}^{\lceil \beta h'' \rceil}(x).$$

It is easy to show that

$$m(\tilde{R}) \leq 2\beta m(R), \quad \forall R \in \mathcal{R}.$$

In order to prove the boundedness of the Hardy–Littlewood maximal function we need the following technical lemma.

Lemma 3.2 *Let $R_1, R_2 \in \mathcal{R}$ with roots x_1, x_2 respectively, such that $R_1 \cap R_2 \neq \emptyset$ and $m(x_1) \geq m(x_2)$. Then*

$$R_2 \subset \tilde{R}_1.$$

Proof If R_1 and R_2 are singletons, then they coincide. If $R_2 = \{x_2\}$, then $R_1 \cap R_2 \neq \emptyset$ implies $x_2 \in R_1 \subset \tilde{R}_1$. If $R_1 = \{x_1\}$, then $R_1 \cap R_2 \neq \emptyset$ implies $x_1 \in R_2$, but, since $m(x_1) \geq m(x_2)$, it follows $x_1 = x_2$.

Consider now the case when $R_1 = R_{h_1'}^{h_1''}(x_1)$, $R_2 = R_{h_2'}^{h_2''}(x_2)$ are both not singletons. Define $\ell_i = \ell(x_i)$. Since $R_1 \cap R_2 \neq \emptyset$, there exists $\overline{x} \in R_1 \cap R_2$; hence $\ell(x_i) \geq \ell(\overline{x})$. It is easy to see that the existence of $\overline{x}$ implies that x_2 lies below x_1 and in particular $\ell_2 \leq \ell_1$. Moreover, $\ell_i - h_i'' + 1 \leq \ell(\overline{x}) \leq \ell_j - h_j'$, with $i, j = 1, 2$. Thus

$$\begin{cases} \ell_1 - \ell_2 \geq h_1' - h_2'' + 1, \\ \ell_1 - \ell_2 \leq h_1'' - h_2' - 1. \end{cases} \tag{10}$$

Let x be a vertex in R_2. By definition we have $h_2' \le \ell_2 - \ell(x) \le h_2'' - 1$. By Eq. 10

$$\ell_1 - \ell(x) = \ell_1 - \ell_2 + \ell_2 - \ell(x) < \beta(h_1'' - \tfrac{h_2''}{\beta} + 1) + h_2'' - 1 < \beta h_1'' \le \lceil \beta h_1'' \rceil.$$

Again, by Eq. 10,

$$\ell_1 - \ell(x) = \ell_1 - \ell_2 + \ell_2 - \ell(x) > \tfrac{1}{\beta}(h_1' - \beta h_2' + 1) + h_2' > \tfrac{h_1'}{\beta},$$

hence, we deduce $\ell_1 - \ell(x) \ge \lceil \tfrac{h_1'}{\beta} \rceil$. In conclusion, $x \in \tilde{R}_1$. $\qquad\square$

We remark that

$$\|Mf\|_\infty \le \|f\|_\infty, \qquad \forall f \in L^\infty(m). \tag{11}$$

We can now state the main result of this section.

Theorem 3.3 *The following hold.*

(i) *For all $f \in L^1(m)$ and $\lambda > 0$*

$$m(\{x \in V \ : \ Mf(x) > \lambda\}) \le \frac{2\beta}{\lambda} \|f\|_1;$$

(ii) *for every $p \in (1, +\infty)$, M is bounded on $L^p(m)$ with constant at most*
$$2\left(2\beta \frac{p}{p-1}\right)^{1/p}.$$

Proof Property (ii) follows by (i) and Eq. 11 by the Marcinkiewicz interpolation Theorem. For proving (i), by means of Lemma 3.2, we can follow closely the proof of [14, Th. 3.1]. Let $\lambda > 0$, $f \in L^1(m)$ and set

$$\Omega_\lambda = \{x \in V \ : \ Mf(x) > \lambda\}, \quad S_0 = \left\{R \in \mathcal{R} \ : \ \tfrac{1}{m(R)} \int_R |f| \, dm > \lambda\right\}.$$

For all $R \in S_0$ we have

$$m(x_R) \le m(R) < \frac{1}{\lambda} \|f\|_1.$$

S_0 is countable hence we can introduce an order. We say that $R \ge Q$ if $m(x_R) \ge m(x_Q)$. Let R_1 be the maximal trapezoid in S_0 with respect to $\ge$ (it exists because of the previous estimate) which appears first in the order. Define $S_1 = \{R \in S_0 \ : \ R \cap R_1 = \emptyset\}$.
Let R_2 be the maximal admissible trapezoid in S_1 which appears first in the ordering. So we can define inductively the sequences

$$S_{i+1} = \{R \in S_i \ : \ R \cap R_j = \emptyset, \ j \le i\},$$

and $R_{i+1} \in S_{i+1}$ is the maximal trapezoid with respect to $\ge$ which appears first in the ordering. We claim that

$$\forall R \in S_0 \ \exists R_i \ : \ R \cap R_i \ne \emptyset, \ m(x_{R_i}) \ge m(x_R). \tag{12}$$

By Lemma 3.2, Eq. 12 in particular implies that $R \subset \tilde{R}_i$. Now we prove the claim: it suffices to show that there exists $j \in \mathbb{N}$ such that $R \in S_j \setminus S_{j+1}$. By contradiction, if such a j does not exist, then $\exists k$ such that S_k contains infinite admissible trapezoids $\{T_l\}_l$ such that $T_l \cap T_i = \emptyset$ if $i \ne j$, $m(x_{T_l}) = \max\{m(x_R) : R \in S_k\}$, $T_l \cap R = \emptyset$. Now we set

$$R_k = T_1, ..., R_{k+i} = T_{i+1}, ...,$$

then

$$\sum_{i=k}^{+\infty} m(x_{R_i}) \leq \sum_{i=k}^{+\infty} m(R_i) \leq \sum_{i=k}^{\infty} \frac{1}{\lambda} \int_{R_i} |f| \, dm \leq \frac{\|f\|_1}{\lambda},$$

and the left hand side is infinite. Thus the claim is proved. Define $E = \cup_i \tilde{R}_i$ and notice that $E^c \subset \Omega_\lambda^c$. Indeed if $x \in E^c$ and $R \in \mathcal{R}$ contains x then $R \notin S_0$. We conclude that for $x \in E^c$

$$M(f)(x) = \sup_{R \ni x, R \notin S_0} \frac{1}{m(R)} \int_R |f| \, dm \leq \lambda,$$

hence $x \notin \Omega_\lambda$. In conclusion

$$m(\Omega_\lambda) \leq m(E) \leq \sum_i m(\tilde{R}_i) \leq 2\beta \sum_i m(R_i) \leq 2\beta \frac{1}{\lambda} \|f\|_1.$$

$\square$

3.4 Calderón–Zygmund Decomposition

The aim of this section is to introduce a Calderón–Zygmund decomposition in our setting. We initially prove a preliminary lemma which states the existence of a partition of V consisting of big admissible trapezoids, in the sense that, if we fix any $\sigma > 0$, each set of such a partition has measure larger than σ.

Lemma 3.4 *For all $\sigma > 0$ there exists a partition $\mathcal{P} \subset \mathcal{R}$ of V, such that*

$$m(R) > \sigma, \qquad \forall R \in \mathcal{P}.$$

Proof For all $n \in \mathbb{Z}$ let x_n denote the vertex in g such that $\ell(x_n) = n$. We consider two cases, either $\{m(x_n)\}_{n \in \mathbb{Z}}$ diverges as $n \to +\infty$ or $\{m(x_n)\}_{n \in \mathbb{Z}}$ is bounded. If $m(x_n) \to +\infty$, then there exists $\bar{n} \in \mathbb{N}$ such that $m(x_n) > \sigma c$ for all $n \geq \bar{n}$ where c is as in Eq. 6. For any $y \in V$ set $R_l^y = R_{2^{l-1}}^{2^l}(y)$ for all $l \in \mathbb{N}$. We define $\mathcal{P}$ as

$$\mathcal{P} = \{R_l^y : l \in \mathbb{N}, \ y \in \{x_{\bar{n}-1}\} \cup (s(x_n) \setminus g), \ n \geq \bar{n}\} \cup \{s(x_j) : j \geq \bar{n}\}.$$

This concludes the proof when $\{m(x_n)\}_{n \in \mathbb{Z}}$ diverges.

Now assume that $\{m(x_n)\}_{n \in \mathbb{Z}}$ is bounded. By Eq. 7, there are finitely many vertices $y \in g$ such that $\ell(y) \geq 0$ and $q(y) \geq 2$. Let x_l denote the vertex in g with maximum level such that $q(x_l) \geq 2$. By the definition of flow we have that $m(x_n) = m(x_l)$ if $n \geq l$. First, notice that there exists $p \in \mathbb{N}$ such that $2^{p-1} m(x_l) > \sigma$, thus we can cover the upper part of the tree with trapezoids $U_k = R_{2^{p-1}}^{2^p}(x_{l+2^{p-1}k})$ where $k \geq 1$ and $m(U_k) = 2^{p-1} m(x_l) > \sigma$ for all k. Subsequently, we cover the lower part of the tree with trapezoids $L_j = R_{2^j}^{2^{j+1}}(x_{l+2^{p-1}})$ with $j \geq p$. Observe that $m(L_j) = 2^j m(x_l) \geq 2^p m(x_l) > \sigma$. We conclude by defining

$$\mathcal{P} = \{U_k\}_{k \geq 1} \bigcup \{L_j\}_{j \geq p}.$$

$\square$

Next lemma provides a quite general procedure to determine a family of stopping sets for a given testing condition on the size of the L^1 mean of a function. Several results in the paper will rely on such a scheme as a basic step.

Lemma 3.5 *Let $f : V \to \mathbb{C}$, $\alpha > 0$ and $R \in \mathcal{R}$ such that $\frac{1}{m(R)} \int_R |f| \, dm < \alpha$. Then, there exists a family $\mathcal{F}$ of disjoint admissible trapezoids such that for each $E \in \mathcal{F}$ the following hold:*

(i) $\frac{1}{m(E)} \int_E |f| \, dm \geq \alpha$;

(ii) $\frac{1}{m(E)} \int_E |f| \, dm < \widetilde{C}\alpha$;

(iii) *if $x \in R \setminus \bigcup_{E \in \mathcal{F}} E$, then $|f(x)| < \alpha$.*

Proof We apply the decomposition algorithm to R: if $Q \in \mathcal{F}(R, 1)$ is such that $\frac{1}{m(Q)} \int_Q |f| \, dm \geq \alpha$ then we stop and declare $Q \in \mathcal{F}$, otherwise, if Q is divisible (i.e., it is not a singleton) we split it up applying again the decomposition algorithm. We iterate the above reasoning until R is partitioned in some *stopping sets* E such that $\frac{1}{m(E)} \int_E |f| \, dm \geq \alpha$ (some of which may be singletons) and some singletons x at which $|f(x)| = \frac{1}{m(x)} \int_{\{x\}} |f| \, dm < \alpha$. Let $\mathcal{F}$ be the family of the stopping sets. Then (i) and (iii) hold by construction. To prove (ii): for each $E \in \mathcal{F}$ there exists $k \geq 1$ such that $E \in \mathcal{F}(R, k)$. Let E' be the unique set in $\mathcal{F}(R, k - 1)$ such that $E \in \mathcal{F}(E', 1)$. Then $E \subset E', m(E') \leq \widetilde{C}m(E)$ and, since E' is not a stopping set, $\frac{1}{m(E')} \int_{E'} |f| \, dm < \alpha$. Hence

$$\frac{1}{m(E)} \int_E |f| \, dm \leq \frac{\widetilde{C}}{m(E')} \int_{E'} |f| \, dm < \widetilde{C}\alpha.$$

$\square$

Now we present the main result of this section, namely the Calderón–Zygmund decomposition of integrable functions.

Theorem 3.6 (Calderón–Zygmund decomposition) *For every $f \in L^1(m)$ and $\alpha > 0$, there exist a family $\{E_i\}$ of disjoint admissible trapezoids and functions g, b^i such that $f = g + \sum_i b^i$ and*

(i) $|g| \leq \widetilde{C}\alpha$;

(ii) $b^i = 0$ on $(E_i)^c$;

(iii) $\|b^i\|_1 \leq 2\widetilde{C}\alpha m(E_i)$ and $\int_{E_i} b^i \, dm = 0$;

(iv) $\sum_i m(E_i) \leq \frac{\|f\|_1}{\alpha}$.

Proof Let $\mathcal{P} \subset \mathcal{R}$ be a partition of V such that for all $R \in \mathcal{P}$ we have $m(R) > \frac{\|f\|_1}{\alpha}$. Then, for every $R \in \mathcal{P}$, it holds $\frac{1}{m(R)} \int_R |f| \, dm < \alpha$, and we can apply Lemma 3.5. Let $\mathcal{F}(R)$ be the family of stopping sets generated by R and let $\{E_i\}$ be a listing of the sets belonging to $\mathcal{F}(R)$ for some $R \in \mathcal{R}$. We define now

$$g(x) = \begin{cases} \frac{1}{m(E_i)} \int_{E_i} f \, dm & \text{if } x \in \bigcup_i E_i, \\ f(x) & \text{else}, \end{cases}$$

$$b^i(x) = \left(f(x) - \frac{1}{m(E_i)} \int_{E_i} f \, dm \right) \chi_{E_i}(x).$$

By Lemma 3.5, $|g(x)| \leq \widetilde{C}\alpha$. Every b^i is supported in E_i and $\int_{E_i} b^i \, dm = 0$. Moreover,

$$\|b^i\|_1 \leq 2 \int_{E_i} |f| \, dm \leq 2\widetilde{C}\alpha m(E_i),$$

and

$$\sum_i m(E_i) \leq \frac{1}{\alpha} \sum_i \int_{E_i} |f| \, dm \leq \frac{\|f\|_1}{\alpha}.$$

$\square$

4 *BMO* and Hardy Spaces

This section is devoted to the definitions and the study of properties of BMO and Hardy spaces in our setting.

4.1 *BMO* Spaces

We now introduce the space of bounded mean oscillation functions. In the following we denote by f_R the integral average of f on R, i.e.,

$$f_R = \frac{1}{m(R)} \int_R f \, dm.$$

Definition 4.1 Given $q \in [1, +\infty)$ we define $BMO_q(m)$ as the space of all functions $f : V \to \mathbb{C}$ such that

$$\|f\|_{BMO_q} = \sup_{R \in \mathcal{R}} \left(\frac{1}{m(R)} \int_R |f - f_R|^q \, dm \right)^{1/q} < \infty,$$

quotiented over constant functions. It can be easily shown that $(BMO_q(m), \|\cdot\|_{BMO_q})$ is a Banach space.

As an immediate consequence of the Hölder's inequality we have

$$\|f\|_{BMO_1} \leq \|f\|_{BMO_q},$$

thus $BMO_q(m) \subset BMO_1(m)$. To prove the reverse inclusion we shall first show that a John-Nirenberg inequality holds in our setting.

Theorem 4.2 (John-Nirenberg inequality) *There exist $\eta, A > 0$ such that, for all $f \in BMO_1(m)$:*

(i) $\sup_{R \in \mathcal{R}_2^\beta} \frac{1}{m(R)} \int_R \exp\left(\frac{\eta}{\|f\|_{BMO_1}} |f - f_R| \right) dm \leq A;$

(ii) $m(\{x \in R : |f(x) - f_R| > t\|f\|_{BMO_1}\}) \leq A e^{-\eta t} m(R), \qquad \forall t > 0 \text{ and } R \in \mathcal{R}.$

Proof Suppose $f : V \to \mathbb{C}$ is non constant, otherwise the result is trivial. Let $R_0 \in \mathcal{R}$. If $R_0 = \{x_0\}$, then $f_{R_0} = f(x_0)$ and

$$\frac{1}{m(R_0)} \int_{R_0} \exp\left(\frac{\eta}{\|f\|_{BMO_1}} |f - f_{R_0}| \right) dm = 1,$$

thus it is sufficient to choose $A \geq 1$.
If $R_0 \neq \{x_0\}$, we have

$$\frac{1}{m(R_0)} \int_{R_0} |f - f_{R_0}| \, dm < 2\|f\|_{BMO_1}.$$

Applying Lemma 3.5 to the function $f - f_{R_0}$ with $\alpha = 2\|f\|_{BMO_1}$, we get a family $\mathcal{F}$ of disjoint stopping sets contained in R_0 satisfying properties (i), (ii) and (iii) in the lemma. In particular by (i) follows

$$m\left(\bigcup_{E \in \mathcal{F}} E\right) = \sum_{E \in \mathcal{F}} m(E) < \frac{1}{2\|f\|_{BMO_1}} \sum_{E \in \mathcal{F}} \int_E |f - f_{R_0}|\, dm$$

$$\leq \frac{1}{2\|f\|_{BMO_1}} \int_{R_0} |f - f_{R_0}|\, dm \leq \frac{m(R_0)}{2}. \tag{13}$$

For each stopping set $E \in \mathcal{F}$ we have

$$|f_E - f_{R_0}| \leq |f_E - f_{E'}| + |f_{E'} - f_{R_0}| \leq \frac{1}{m(E)} \int_E |f - f_{E'}|\, dm + \frac{1}{m(E')} \int_{E'} |f - f_{R_0}|\, dm$$

$$\leq \frac{\widetilde{C}}{m(E')} \int_{E'} |f - f_{E'}|\, dm + 2\|f\|_{BMO_1} \leq (\widetilde{C} + 2)\|f\|_{BMO_1}. \tag{14}$$

Now, suppose first $f \in L^\infty(m)$, and for $t > 0$ we define

$$F(t) = \sup_{R \in \mathcal{R}_2^\beta} \frac{1}{m(R)} \int_R \exp\left(\frac{t}{\|f\|_{BMO_1}} |f - f_R|\right) dm.$$

Then $|f - f_R| \leq 2\|f\|_\infty$, from which follows

$$F(t) \leq \exp\left(\frac{2t\|f\|_\infty}{\|f\|_{BMO_1}}\right) < +\infty, \quad \forall t > 0.$$

We estimate

$$\frac{1}{m(R_0)} \int_{R_0} \exp\left(\frac{t}{\|f\|_{BMO_1}} |f - f_{R_0}|\right) dm \leq \frac{1}{m(R_0)} \int_{R_0 \setminus \cup_{E \in \mathcal{F}} E} \exp(2t)\, dm$$

$$+ \frac{1}{m(R_0)} \sum_{E \in \mathcal{F}} \int_E \exp\left(\frac{t}{\|f\|_{BMO_1}} |f - f_E|\right) \exp\left(\frac{t}{\|f\|_{BMO_1}} |f_E - f_{R_0}|\right) dm. \tag{15}$$

Using Eq. 14 we dominate the last expression in Eq. 15 with

$$\exp(2t) + \frac{1}{m(R_0)} \sum_{E \in \mathcal{F}} \int_E \exp\left((\widetilde{C} + 2)t\right) \exp\left(\frac{t}{\|f\|_{BMO_1}} |f - f_E|\right) dm$$

$$\leq \exp(2t) + \exp\left((\widetilde{C} + 2)t\right) \frac{1}{m(R_0)} \sum_{E \in \mathcal{F}} m(E) F(t)$$

$$\leq \exp(2t) + \exp\left((\widetilde{C} + 2)t\right) \frac{F(t)}{2},$$

where the last inequality is verified by Eq. 13. We conclude that $F(t) \leq \frac{2e^{2t}}{2 - e^{(\widetilde{C}+2)t}}$, hence there exist $\eta, A > 0$ such that $F(\eta) \leq A$. This ends the proof when f is a bounded function. For the general case, let $f \in BMO_1(m)$ and for all $k \in \mathbb{N}$ and $x \in V$ define

$$f_k(x) = \begin{cases} f(x) & |f(x)| \leq k, \\ \frac{f(x)}{|f(x)|} k & |f(x)| > k. \end{cases}$$

It is readily seen that $f_k \in L^\infty(m)$, $f_k \to f$ pointwise on V, $(f_k)_R \to f_R$ and there exists a positive constant c' such that $\|f_k\|_{BMO_1} \leq c'\|f\|_{BMO_1}$. We have that

$$\frac{1}{m(R)} \int_R \exp\left(\frac{\eta}{c'\|f\|_{BMO_1}} |f_k - (f_k)_R|\right) dm \leq \frac{1}{m(R)} \int_R \exp\left(\frac{\eta}{\|f_k\|_{BMO_1}} |f_k - (f_k)_R|\right) dm \leq C.$$

Passing to the limit, we deduce *(i)* by the dominated convergence theorem. In order to prove *(ii)*, notice that

$$m(\{x \in R : |f(x) - f_R| > t\|f\|_{BMO_1}\}) = m(\{x \in R : \exp\left(\frac{\eta}{\|f\|_{BMO_1}}|f(x) - f_R|\right) > e^{\eta t}\})$$

$$\leq e^{-\eta t} \int_R \exp\left(\frac{\eta}{\|f\|_{BMO_1}}|f - f_R|\right) dm \leq A e^{-\eta t} m(R),$$

where the last inequality follows by *(i)*.   □

A remarkable consequence of Theorem 4.2 is the equivalence of the $BMO_q(m)$ spaces, $q \in [1, +\infty)$.

Corollary 4.3 *For all $1 < q < +\infty$ there exists a constant B_q depending only on q such that*

$$\|f\|_{BMO_q} \leq B_q \|f\|_{BMO_1}, \quad \forall f \in BMO_1(m).$$

Proof

$$\frac{1}{m(R)} \int_R |f - f_R|^q \, dm = \frac{q}{m(R)} \int_0^\infty \alpha^{q-1} m(\{x \in R : |f - f_R|(x) > \alpha\}) \, d\alpha$$

$$\leq q \int_0^\infty \alpha^{q-1} A e^{-\eta \alpha/\|f\|_{BMO_1}} \, d\alpha \leq q A \left(\frac{\|f\|_{BMO_1}}{\eta}\right)^q \Gamma(q).$$

We conclude by choosing $B_q = (qA\Gamma(q))^{1/q}/\eta$.   □

Henceforward, let $BMO(m)$ denote the space $BMO_1(m)$.

4.2 Hardy Spaces

In this section we introduce atomic Hardy spaces. In our setting, atoms are supported in admissible trapezoids.

Definition 4.4 A function a is a $(1, p)$-atom for $p \in (1, +\infty]$ if the following hold

   (i) a is supported in a set $R \in \mathcal{R}$;
   (ii) $\|a\|_p \leq m(R)^{1/p-1}$;
   (iii) $\int_R a \, dm = 0$.

Definition 4.5 The Hardy space $H^{1,p}(m)$ is the space of all the function $g \in L^1(m)$ such that $g = \sum_j \lambda_j a_j$ where a_j are $(1, p)$ atoms and λ_j are complex numbers such that $\sum_j |\lambda_j| < +\infty$. We denote by $\|g\|_{H^{1,p}}$ the infimum of $\sum_j |\lambda_j|$ over all the possible decompositions $g = \sum_j \lambda_j a_j$ with a_j $(1, p)$-atoms.

We also introduce the subspace

$$H_{\text{fin}}^{1,p}(m) = \left\{g \in H^{1,p}(m) : g = \sum_{j=1}^N \lambda_j a_j, \ N \in \mathbb{N}\right\}.$$

The next result yields the equivalence of the $H^{1,p}(m)$ spaces when $p \in (1, +\infty]$. It is readily seen that $H^{1,\infty}(m) \subset H^{1,p}(m)$. For the converse, we use a variant of the Calderón–Zygmund decomposition, as follows.

Proposition 4.6 *For any $p \in (1, +\infty)$ there exists $A_p > 0$ such that the following estimate holds*

$$\|f\|_{H^{1,\infty}} \leq A_p \|f\|_{H^{1,p}}, \qquad \forall f \in H^{1,p}(m).$$

Hence $H^{1,p}(m) = H^{1,\infty}(m)$ and the norms $\| \cdot \|_{H^{1,\infty}}$ and $\| \cdot \|_{H^{1,p}}$ are equivalent.

Proof It suffices to prove that there exists a constant A_p depending only on $p \in (1, +\infty)$ such that, for every $(1, p)$-atom a, one has

$$\|a\|_{H^{1,\infty}} \leq A_p. \tag{16}$$

Let a be a $(1, p)$-atom. We have that $\mathrm{supp}(a) \subset Q \in \mathcal{R}$, $\|a\|_p \leq m(Q)^{1/p-1}$, $\int_Q a \, dm = 0$. We define $b = m(Q)a$; we claim that $\forall n \in \mathbb{N}$, we can write

$$b = \sum_{l=0}^{n-1} \widetilde{C}^{1/p} \alpha^{l+1} \sum_{j_l \in \mathbb{N}^l} m(R_{j_l}) a_{j_l} + \sum_{j_n \in \mathbb{N}^n} f_{j_n},$$

where $\alpha > 0$ is a constant to be chosen later on, $\widetilde{C}$ is as in Proposition 3.1 and

(i) a_{j_l} is a $(1, \infty)$-atom supported in R_{j_l},
(ii) $\mathrm{supp}\, f_{j_n} \subset R_{j_n}$, $\int_{R_{j_n}} f_{j_n} \, dm = 0$,
(iii) $\left(\frac{1}{m(R_{j_n})} \int_{R_{j_n}} |f_{j_n}|^p \, dm \right)^{1/p} \leq 2\widetilde{C}^{1/p} \alpha^n$,
(iv) $\sum_{j_n} \|f_{j_n}\|_p^p \leq 2^{pn} \|b\|_p^p$,
(v) $|f_{j_n}(x)| \leq b(x) + \widetilde{C}^{1/p} \alpha^n 2^{n-1}$,
(vi) $\sum_{j_n} m(R_{j_n}) \leq 2^{p(n-1)} \alpha^{-np} \|b\|_p^p$.

Assume the claim holds. Then

$$\left\| \sum_{j_n \in \mathbb{N}^n} f_{j_n} \right\|_1 \leq \sum m(R_{j_n})^{1/p'} \|f_{j_n}\|_p \leq 2 \sum m(R_{j_n})^{1/p'} m(R_{j_n})^{1/p} \widetilde{C}^{1/p} \alpha^n$$

$$\leq 2\widetilde{C}^{1/p} \alpha^n 2^{p(n-1)} \alpha^{-np} \|b\|_p^p \leq 2\widetilde{C}^{1/p} 2^{-p} (\alpha^{-p} 2^p)^n m(Q),$$

the last quantity tends to zero as $n \to +\infty$ if $\alpha > 2^{\frac{p}{p-1}}$. The previous computation shows that

$$b = \sum_{l=0}^{\infty} \widetilde{C}^{1/p} \alpha^{l+1} \sum_{j_l \in \mathbb{N}^l} m(R_{j_l}) a_{j_l}$$

where the series converges in $L^1(m)$. By properties (vi) we have

$$\sum_{l=0}^{\infty} \widetilde{C}^{1/p} \alpha^{l+1} \sum_{j_l \in \mathbb{N}^l} m(R_{j_l}) \leq \sum_{l=0}^{\infty} \widetilde{C}^{1/p} \alpha^{l+1} 2^{p(l-1)} \alpha^{-lp} m(Q) = A_p m(Q),$$

if $\alpha > 2^{p/(p-1)}$ and we conclude that $\|a\|_{H^{1,\infty}} \leq A_p$.
We now prove the claim by induction. Fix $n = 1$ and notice that

$$\frac{1}{m(Q)} \int_Q |b|^p \, dm = \frac{1}{m(Q)} m(Q)^p \int_Q |a|^p \, dm \leq 1 < \alpha^p.$$

Apply Lemma 3.5 to the function $|b|^p$ with the constant α^p, call $\{R_i\}_i$ the family of stopping sets and set $E = \cup_i R_i$. Define

$$b = g + \sum_i f_i, \quad f_i = \left[b - \frac{1}{m(R_i)} \int_{R_i} b \, dm\right] \chi_{R_i}.$$

By definition of R_i, $|g| < \alpha$ on E^c, and by the Hölder's inequality and Lemma 3.5, we have

$$\left|\frac{1}{m(R_i)} \int_{R_i} b \, dm\right| < \widetilde{C}^{1/p} \alpha, \tag{17}$$

which yields

$$\|f_i\|_p < \left(\int_{R_i} |b|^p \, dm\right)^{1/p} + \widetilde{C}^{1/p} \alpha m(R_i)^{1/p} < 2\widetilde{C}^{1/p} \alpha m(R_i)^{1/p}.$$

Moreover, by Eq. 17

$$|g(x)| \leq \widetilde{C}^{1/p} \alpha \qquad \text{if } x \in R_i,$$

thus $a_0 = (\widetilde{C}^{1/p} \alpha m(Q))^{-1} g$ is a $(1, \infty)$-atom. We can write $b = g + \sum_i f_i = \widetilde{C}^{1/p} \alpha m(Q) a_0 + \sum_i f_i$, obviously $\mathrm{supp} f_i \subset R_i$, $\int f_i \, dm = 0$ and $\|f_i\|_p \leq 2\widetilde{C}^{1/p} \alpha m(R_i)^{1/p}$. By definition of stopping set and f_i we have

$$\sum_i m(R_i) \leq \frac{\|b\|_p^p}{\alpha^p}, \quad \|f_i\|_p \leq 2\|b\|_{L^p(R_i)},$$

hence

$$\sum_i \|f_i\|_p^p \leq 2^p \|b\|_p^p,$$

and the claim is verified.

We now assume that the claim holds for $n \in \mathbb{N}$. Then, for all $j_n \in \mathbb{N}^n$,

$$\frac{1}{m(R_{j_n})} \int_{R_{j_n}} |f_{j_n}|^p \, dm \leq 2^p \widetilde{C} \alpha^{np} < \alpha^{(n+1)p},$$

if we choose $\alpha > 2\widetilde{C}^{1/p}$. We apply Lemma 3.5 to each R_{j_n} producing stopping sets $R_{j_n i}$, $i \in \mathbb{N}$, such that

$$\alpha^{(n+1)p} \leq \frac{1}{m(R_{j_n i})} \int_{R_{j_n i}} |f_{j_n}|^p \, dm < \widetilde{C} \alpha^{(n+1)p}.$$

We define

$$f_{j_n i} = \left[f_{j_n} - \frac{1}{m(R_{j_n i})} \int_{R_{j_n i}} f_{j_n} \, dm\right] \chi_{R_{j_n i}}, \quad g_{j_n} = f_{j_n} - \sum_{i \in \mathbb{N}} f_{j_n i}.$$

Then, arguing as above, $a_{j_n} = (\widetilde{C}^{1/p} \alpha^{(n+1)p} m(R_{j_n}))^{-1} g_{j_n}$ is a $(1, \infty)$-atom, $f_{j_n i}$ is supported in $R_{j_n i}$ and has zero integral,

$$\left(\frac{1}{m(R_{j_n i})} \int_{R_{j_n i}} |f_{j_n}|^p \, dm\right)^{1/p} \leq \widetilde{C}^{1/p} \alpha^{n+1} < 2\widetilde{C}^{1/p} \alpha^{n+1},$$

and

$$|f_{j_n i}(x)| \leq |f_{j_n}(x)| + \widetilde{C}^{1/p} \alpha^{n+1} \leq |b(x)| + \widetilde{C}^{1/p} \alpha^n 2^{n-1} + \widetilde{C}^{1/p} \alpha^{n+1} \leq |b(x)| + \widetilde{C}^{1/p} \alpha^{n+1} 2^n.$$

We deduce that

$$\sum_{j_n i} \|f_{j_n i}\|_p^p \le \sum_{j_n} 2^p \|f_{j_n}\|_p^p \le 2^{p(n+1)} \|b\|_p^p,$$

$$\sum_{j_n i} m(R_{j_n i}) \le \frac{1}{\alpha^{(n+1)p}} \sum_{j_n} \sum_i \int_{R_{j_n i}} |f_{j_n}|^p \, dm \le \frac{1}{\alpha^{(n+1)p}} \sum_{j_n} \|f_{j_n}\|_p^p \le \frac{1}{\alpha^{(n+1)p}} 2^{pn} \|b\|_p^p$$

and this concludes the proof. $\qquad\square$

In the sequel we write $H^1(m)$ in place of $H^{1,\infty}(m)$ and $H^1_{\text{fin}}(m)$ in place of $H^{1,\infty}_{\text{fin}}(m)$.

Remark 4.7 We now show that the Hardy space $H^1(m)$ does not depend on the choice of β. Fix $12 \le \beta < \beta'$ and denote by $\mathcal{R}$ and $\mathcal{R}'$ the family of admissible trapezoids corresponding to the parameters β and β', respectively. We call $H^1_\beta(m)$ and $H^1_{\beta'}(m)$ the correspondent Hardy spaces with atoms supported in sets in $\mathcal{R}$ and $\mathcal{R}'$ respectively. It is clear that $H^1_\beta(m) \subset H^1_{\beta'}(m)$. For the reverse inclusion, we prove that any $(1,\infty)$-atom in $H^1_{\beta'}(m)$ can be decomposed as the sum of multiples of $(1,\infty)$-atoms in $H^1_\beta(m)$ in such a way that the norm is uniformly bounded.

First assume $\beta' \le 2\beta$. Consider a $(1,\infty)$-atom $a \in H^1_{\beta'}(m)$ supported in a set $R = R^{h''}_{h'}(x) \in \mathcal{R}' \setminus \mathcal{R}$.

By applying the decomposition algorithm to R we obtain $R_1 = R^{2h'}_{h'}(x)$ and $R_2 = R^{h''}_{2h'}(x)$. Now we call $T = R^{4h'}_{2h'}(x)$, $T_1 = R^{4h'}_{h'}(x)$, $T_2 = R_2$. Obviously $R_1, R_2, T, T_1 \in \mathcal{R}$. We define

$$\varphi_i = a\chi_{R_i} - \left(\frac{1}{m(T)} \int_V a\chi_{R_i} \, dm\right)\chi_T, \quad i = 1, 2.$$

We have that $\int_V \varphi_i \, dm = 0$ for $i = 1, 2$ and $\varphi_1 + \varphi_2 = a$ as consequence of the vanishing integral of a. Moreover,

$$\|\varphi_i\|_\infty \le 2\|a\|_\infty \le \frac{2}{m(R)} \le \frac{2}{m(T_i)},$$

for $i = 1, 2$. Observe that φ_i is supported in $R_i \cup T = T_i$ because $4h' < h''$. Thus $\varphi_i/2$ is a $(1,\infty)$-atom supported in $T_i \in \mathcal{R}$ and $H^1_{\beta'}(m) \subset H^1_\beta(m)$.

Suppose now that $2^{n-1}\beta \le \beta' \le 2^n\beta$ for some $n > 1$. We observe that $H^1_{\beta'}(m) = H^1_{\beta'/2}(m) = H^1_{\beta'/4}(m) \cdots = H^1_{\beta'/2^n}(m)$. Thus $H^1_{\beta'}(m) = H^1_\beta(m)$ and this concludes the proof.

Remark 4.8 If we choose $T = \mathbb{T}_{q+1}$ and $\mu(\cdot) = q^{\ell(\cdot)}$ as a particular flow measure, it can be used a similar argument in order to show the equivalence of $H^1_\beta(\mu)$ and the space $H^1(\mu)$ introduced in [2].

4.3 Duality Between $H^1(m)$ and $BMO(m)$

We now establish the duality between $H^1(m)$ and $BMO(m)$. We first need a lemma which provides a covering of V made by an increasing family of admissible trapezoids.

Lemma 4.9 *There exists a family $\{R_j\}_j \subset \mathcal{R}$ such that $R_j \subset R_{j+1}$ and $\cup_j R_j = V$.*

Proof Let $R_0 = \{x_0\}$, and define R_j to be the output of the expansion algorithm applied to R_{j-1} for $j \geq 1$. About vertical expansions, choose at random whether to expand up or down for the first occurring one (which is the one producing R_4 out of R_3) and then always alternate them (for example, if we decide to extend R_3 down, the next vertical expansion will be up). Observe that a vertical expansion always needs to be followed by a vertical one. The opposite is not true, but still horizontal and vertical expansions will definitely alternate since, for any given $R_{h'}^{h''}(x_0) \in \mathcal{R}$, it holds $\frac{h''+k}{h'+k} < 3$ for k large enough. It is then clear that $R_j \subset R_{j+1}$ and $\cup_{j \geq 0} R_j = V$. □

Theorem 4.10 (Duality between $H^1(m)$ and $BMO(m)$) *(i) Suppose $f \in BMO(m)$. Then the linear functional ℓ given by*

$$\ell(g) = \int_V fg \, dm,$$

initially defined on the dense subspace $H_{\text{fin}}^1(m)$, has a unique bounded extension to $H^1(m)$ and there exists $C > 0$ such that

$$\|\ell\|_{(H^1)'} \leq C\|f\|_{BMO}.$$

(ii) Conversely, every continuous linear functional ℓ on $H^1(m)$ can be realized as above, with $f \in BMO(m)$, and there exists $C > 0$ such that

$$\|f\|_{BMO} \leq C\|\ell\|_{(H^1)'}.$$

Proof For the proof of (i) we can closely follow [11, 13] for the Euclidean setting.

We prove (ii). For every $R \in \mathcal{R}$ we denote by L_R^2 the space of all square summable functions supported in R with norm L^2 and by $L_{R,0}^2$ its closed subspace of function with integral zero. Note that $g \in L_{R,0}^2$ implies that g is a multiple of a $(1, 2)$-atom and that $\|g\|_{H^1} \leq A_2 m(R)^{1/2}\|g\|_{L^2}$. Thus, if ℓ is a given functional on $H^1(m)$ then ℓ extends to a linear functional on $L_{R,0}^2$ with norm at most $A_2 m(R)^{1/2}\|\ell\|_{(H^1)'}$ by Proposition 4.6.

Since the dual of $L_{R,0}^2$ is the quotient of L_R^2 module constant functions, by the Riesz theorem, there exists a unique F^R in L_R^2 module constant functions such that

$$\ell(g) = \int_R F^R g \, dm, \quad \forall g \in L_{R,0}^2, \quad \text{and} \quad \|F^R\|_{L^2(R)} \leq A_2 m(R)^{1/2}\|\ell\|_{(H^1)'}.$$

Observe that if $R \subset R'$ then $F^R - F^{R'}$ is constant on R. Let R_j as in Lemma 4.9 for $j = 0, 1, 2, \dots$. Define $f : V \to \mathbb{C}$ by setting

$$f(x) = F^{R_j}(x) - \frac{1}{m(R_1)} \int_{R_1} F^{R_j} \, dm$$

whenever $x \in R_j$. It is easy to verify that the definition of f in unambiguous and $f \in BMO(m)$. □

5 Interpolation and Integral Operators

We will prove here some interpolation results involving Hardy and BMO spaces. The real interpolation results will be essentially a consequence of the Calderón–Zygmund decomposition that we constructed in Section 3.4. To obtain complex interpolation results we will need to discuss the sharp maximal function associated with the admissible trapezoids.

5.1 Real Interpolation

In this subsection we study the real interpolation of $H^1(m)$, $BMO(m)$ and the $L^p(m)$ spaces. We refer the reader to [15] for an overview of the real interpolation results which hold in the classical setting. Our aim is to prove similar results in our context. Note that in our case a maximal characterization of $H^1(m)$ is not available, so that we cannot follow the classical proofs but we shall only exploit the atomic definition of $H^1(m)$. We also notice that the proofs of the our results follow closely those of [26, Section 5].

We first recall some notation of the real interpolation of normed spaces, focusing on the K-method. For the details see [3].

Given two compatible normed spaces A_0 and A_1, for any $t > 0$ and for any $a \in A_0 + A_1$ we define

$$K(t, a; A_0, A_1) = \inf\{\|a_0\|_{A_0} + t\|a_1\|_{A_1} : a = a_0 + a_1, \ a_i \in A_i\}.$$

Take $q \in [1, \infty]$ and $\theta \in (0, 1)$. The *real interpolation space* $[A_0, A_1]_{\theta, q}$ is defined as the set of the elements $a \in A_0 + A_1$ such that

$$\|a\|_{\theta, q} = \begin{cases} \left(\int_0^\infty \left[t^{-\theta} K(t, a; A_0, A_1) \right]^q \frac{dt}{t} \right)^{1/q} & \text{if } 1 \le q < \infty, \\ \|t^{-\theta} K(t, a; A_0, A_1)\|_\infty & \text{if } q = \infty, \end{cases}$$

is finite.

We shall first estimate the K functional of L^p-functions with respect to the couple of spaces $(H^1(m), L^{p_1}(m))$, $1 < p_1 \le \infty$.

Lemma 5.1 *Suppose that $1 < p < p_1 \le \infty$ and let $\theta \in (0, 1)$ be such that $\frac{1}{p} = 1 - \theta + \frac{\theta}{p_1}$. Let f be in $L^p(m)$. The following hold:*

(i) *there exist positive constants D_1, D_2 such that for every $\lambda > 0$ there exists a decomposition $f = g^\lambda + b^\lambda$ in $L^{p_1}(m) + H^1(m)$ such that*

   (i1) $\|g^\lambda\|_\infty \le \widetilde{C}^{1/p} \lambda$ *and, if $p_1 < \infty$, $\|g^\lambda\|_{p_1}^{p_1} \le D_1 \lambda^{p_1 - p} \|f\|_p^p$;*

   (i2) $\|b^\lambda\|_{H^1} \le D_2 \lambda^{1-p} \|f\|_p^p$;

(ii) *there exists a constant $K_p > 0$ such that*

   (ii1) *for any $t > 0$, $K(t, f; H^1(m), L^{p_1}(m)) \le K_p t^\theta \|f\|_p$;*

   (ii2) $f \in [H^1(m), L^{p_1}(m)]_{\theta, \infty}$ *and $\|f\|_{\theta, \infty} \le K_p \|f\|_p$.*

Proof Let f be in $L^p(m)$. We first prove (i). Given a positive λ, let $\{R_i\}_i \subset \mathcal{R}$ be the collection of admissible trapezoids associated with the Calderón–Zygmund decomposition of $|f|^p$ corresponding to the value λ^p. We write

$$f = g^\lambda + b^\lambda = g^\lambda + \sum_i b_i^\lambda = g^\lambda + \sum_i (f - f_{R_i})\chi_{R_i}.$$

We then have

$$\|g^\lambda\|_\infty \le \widetilde{C}^{1/p}\lambda, \qquad \frac{1}{m(R_i)}\int_{R_i}|f|^p\,dm \le \widetilde{C}\lambda^p \qquad \text{and} \qquad |f_{R_i}| \le \widetilde{C}^{1/p}\lambda.$$

If $p_1 < \infty$, then

$$\|g^\lambda\|_{p_1}^{p_1} \le \int_{(\bigcup R_i)^c}|f|^{p_1}\,dm + \sum_i\int_{R_i}|f_{R_i}|^{p_1}\,dm$$

$$\le \int_{(\bigcup R_i)^c}|f|^{p_1-p}|f|^p\,dm + \widetilde{C}^{p_1/p}\lambda^{p_1}\sum_{R_i}m(R_i) \le D_1\lambda^{p_1-p}\|f\|_p^p.$$

Thus $(i1)$ holds. Concerning $(i2)$, for any i, b_i^λ is supported in R_i, has vanishing integral and

$$\|b_i^\lambda\|_p \lesssim m(R_i)^{1/p}\lambda \lesssim \lambda m(R_i)m(R_i)^{-1+1/p}.$$

This shows that $b_i^\lambda \in H^{1,p}(m)$ and $\|b_i^\lambda\|_{H^1} \lesssim \lambda\,m(R_i)$. Since $b^\lambda = \sum_i b_i^\lambda$, b^λ is in $H^1(m)$ and

$$\|b^\lambda\|_{H^1} \lesssim \lambda\sum_i m(R_i) \le D_2\,\lambda\,\frac{\|f\|_p^p}{\lambda^p},$$

as required.

We now prove (ii). Fix $t > 0$. For any positive λ, let $f = g^\lambda + b^\lambda$ be the decomposition of f in $L^{p_1}(m) + H^1(m)$ given by (i). Thus

$$K(t, f; H^1(m), L^{p_1}(m)) \le \inf_{\lambda>0}\big(\|b^\lambda\|_{H^1} + t\|g^\lambda\|_{p_1}\big) \lesssim \inf_{\lambda>0}\big(\lambda^{1-p}\|f\|_p^p + t\,\lambda^{1-p/p_1}\|f\|_p^{p/p_1}\big).$$

Arguing as in [26, p. 292] it follows that there exists a positive constant K_p such that

$$K(t, f; H^1(m), L^{p_1}(m)) \le K_p\,\|f\|_p\,t^\theta,$$

proving $(ii1)$. This implies that

$$\|t^{-\theta}\,K(t, f; H^1(m), L^{p_1}(m))\|_\infty \le K_p\,\|f\|_p,$$

so that $f \in [H^1(m), L^{p_1}(m)]_{\theta,\infty}$ and $\|f\|_{\theta,\infty} \le K_p\|f\|_p$, as required in $(ii2)$. □

Mimicking the proofs of [26, Th. 5.2, Cor. 5.4 and 5.7, Prop. 5.6], we deduce from Lemma 5.1 the subsequent results.

Theorem 5.2 *The following hold:*

(i) *Let $1 < p < p_1 \le \infty$ and $\theta \in (0, 1)$ be such that $\frac{1}{p} = 1 - \theta + \frac{\theta}{p_1}$. Then*

$$\big[H^1(m), L^{p_1}(m)\big]_{\theta,p} = L^p(m).$$

(ii) *Let $1 \le q_1 < q < \infty$ and $\frac{1}{q} = \frac{1-\theta}{q_1}$, with $\theta \in (0, 1)$. Then*

$$\big[L^{q_1}(m), BMO(m)\big]_{\theta,q} = L^q(m).$$

(iii) *Let $1 < q < \infty$ and $\frac{1}{q} = 1 - \theta$, with $\theta \in (0, 1)$. Then*

$$\big[H^1(m), BMO(m)\big]_{\theta,q} = L^q(m).$$

5.2 Sharp Maximal Function

In this section we introduce the sharp maximal function of a function $f : V \to \mathbb{C}$, defined by

$$M^{\#} f(x) = \sup_{R \ni x} \frac{1}{m(R)} \int_R |f - f_R| \, dm,$$

where the supremum is taken over all $R \in \mathcal{R}$ such that $x \in R$. The sharp maximal function is a useful tool to capture the local behaviour of the mean oscillation of a function. Obviously, we have $\|M^{\#} f\|_\infty = \|f\|_{BMO_1}$ and $M^{\#} f \leq 2Mf$ pointwise. By the boundedness of the Hardy–Littlewood maximal function, we easily conclude that, for all $p \in (1, +\infty]$,

$$\|M^{\#}(f)\|_p \leq M_p \|f\|_p, \qquad \forall f \in L^p(m), \tag{18}$$

for some M_p depending only on p.

Now we prove the existence of a dyadic family of partitions of the set of vertices of the tree consisting of admissible trapezoids, by which we will obtain the converse inequality to Eq. 18. We remark that, in a certain sense, such a family is the analogue of the classical family of Euclidean dyadic cubes. Indeed, we shall prove that they share similar properties of set inclusion and of measure comparability. The strategy to obtain the dyadic sets is based on the decomposition and expansion algorithms.

Theorem 5.3 *There exists a family $\{\mathcal{D}_j\}_{j \in \mathbb{Z}}$ of partitions of V consisting of admissible trapezoids such that*

(i) $R \subset R'$ *or* $R \cap R' = \emptyset$ *whenever* $R \in \mathcal{D}_j$, $R' \in \mathcal{D}_k$, $k > j$.
(ii) *For any* $j \in \mathbb{Z}$ *and* $R \in \mathcal{D}_j$, *there exists a unique* $R' \in \mathcal{D}_{j+1}$ *such that* $R \subset R'$ *and* $m(R') \leq \tilde{C} m(R)$.
(iii) *For every* $j \in \mathbb{Z}$, $R \in \mathcal{D}_j$ *can be written as the disjoint union of at most c elements of $\mathcal{D}_{j-1}$, where c is the constant in Eq. 6.*
(iv) *For all* $x \in V$ *there exists* $k = k(x) \in \mathbb{Z}$ *such that* $x \in \mathcal{D}_j$ *for all* $j \leq k$.

Proof Let $\{R_j\}$ be the family of trapezoids described in Lemma 4.9. For each $j \geq 0$, R_j can be used as a base set to produce a partition of V. Let $h'(j), h''(j)$ be the parameters defining R_j. Given a trapezoid R, we write $\mathcal{B}(R)$ for the *brothers* of R, the family of trapezoids of parameters $h'(j), h''(j)$ and root of the same level as x_j, the root of R_j. A partition of the strip of vertices $\{x \in V : \ell(x_j) - h''(j) < \ell(x) \leq \ell(x_j) - h'(j)\}$ is naturally given by $\mathcal{B}(R_j)$. Let $\mathcal{L}$ be the set of indices such that R_ℓ is obtained by vertical expansion of $R_{\ell-1}$ when $\ell \in \mathcal{L}$. It is easily seen that $R_\ell \setminus R_{\ell-1}$ is still an admissible trapezoid, and consequently are all its brothers. For $j \in \mathbb{N}$ we set $\mathcal{D}_j$ to be the collection of all trapezoids R belonging to $\mathcal{B}(R_j)$ or to $\mathcal{B}(R_\ell \setminus R_{\ell-1})$ for some $\ell > j$. Then it is clear that $\mathcal{D}_j$ defines a partition of V. For $j < 0$, we define $\mathcal{D}_j$ to be the family of trapezoids obtained by applying one step of the decomposition algorithm to each trapezoid $R \in \mathcal{D}_{j-1}$. Then the family of partitions $\{\mathcal{D}_j\}_{j \in \mathbb{Z}}$ satisfies all the desired properties: (*i*) and (*ii*) follow from the rules defining the expansion algorithm, (*iii*) and (*iv*) from the ones of the decomposition algorithm and Corollary 2.3. □

We set $\mathcal{D} = \cup_{j \in \mathbb{Z}} \mathcal{D}_j$ and we define the maximal dyadic function of $f : V \to \mathbb{C}$ as

$$M_{\mathcal{D}} f(x) = \sup_{R \ni x} \frac{1}{m(R)} \int_R |f| \, dm,$$

where the supremum is taken over all $R \in \mathcal{D}$ such that $x \in R$. We remark that $M_{\mathcal{D}}(f) \le M(f)$ pointwise on V, thus $M_{\mathcal{D}}$ is of weak-type (1,1). In this section we shall prove that the functions Mf, $M^{\#} f$, $M_{\mathcal{D}} f$ and f are comparable in the L^p norm.

In the proof of the next theorem we follow a standard argument, see for example [13, Th. 7.4.4.] for the correspondent result in the Euclidean setting.

Theorem 5.4 *For all $\gamma > 0$, $\lambda > 0$ and $f : V \to \mathbb{C}$, it holds*

$$m(\{x \in V : M_{\mathcal{D}}(f)(x) > 2\lambda, \, M^{\#}(f)(x) < \gamma\lambda\}) \le C' \gamma m(\{x \in V : M_{\mathcal{D}}(f)(x) > \lambda\}),$$

where $C' = 2\beta \widetilde{C}$.

Proof We can assume that $\Omega_\lambda = \{x \in V : M_{\mathcal{D}}(f)(x) > \lambda\}$ has finite measure. Hence for all $x \in \Omega_\lambda$, there exists $R_x \in \mathcal{D}$ that is maximal with respect to set inclusion, such that $x \in R_x$ and

$$\frac{1}{m(R_x)} \int_{R_x} |f| \, dm > \lambda.$$

Notice that if $y \in R_x$, then $R_x = R_y$ because maximal trapezoids are disjoint. Hence it is sufficient to show that for a given R_x

$$m(\{y \in R_x : M_{\mathcal{D}} f(y) > 2\lambda, \, M^{\#} f(y) < \gamma\lambda\}) \le C' \gamma m(R_x). \tag{19}$$

Fix x and $y \in R_x$ such that $M_{\mathcal{D}}(f)(y) > 2\lambda$, then the supremum

$$\sup_{R \ni y} \frac{1}{m(R)} \int_R |f| \, dm$$

is taken over all the dyadic trapezoids R which contain R_x or are contained in R_x. If Q strictly contains R_x, then by the maximality of R_x, we get

$$\frac{1}{m(Q)} \int_Q |f| \, dm \le \lambda.$$

Thus

$$M_{\mathcal{D}} f(x) = M_{\mathcal{D}}(f \chi_{R_x})(x).$$

Let R'_x be the dyadic set of minimal scale such that $R_x \subsetneq R'_x$. It follows

$$M_{\mathcal{D}}\left((f - f_{R'_x}) \chi_{R_x} \right)(x) > M_{\mathcal{D}}(f \chi_{R_x})(x) - |f_{R'_x}| > 2\lambda - \lambda = \lambda.$$

We conclude that

$$m(\{y \in R_x : M_{\mathcal{D}} f(y) > 2\lambda\}) \le m(\{y \in R_x : M_{\mathcal{D}}\left((f - f_{R'_x}) \chi_{R_x} \right)(y) > \lambda\}). \tag{20}$$

We know that $M_{\mathcal{D}}$ is of weak type (1,1), thus we control the last expression in Eq. 20 with

$$\frac{2\beta}{\lambda} \int_{R_x} |f - f_{R'_x}| \, dm \le \frac{2\widetilde{C}\beta}{\lambda} \frac{m(R_x)}{m(R'_x)} \int_{R'_x} |f - f_{R'_x}| \, dm \le \frac{2\widetilde{C}\beta}{\lambda} m(R_x) M^{\#}(f)(\xi_x), \tag{21}$$

where $\xi_x \in R_x$. We can assume that for some $\xi_x \in R_x$ it holds

$$M^{\#}(f)(\xi_x) \leq \gamma\lambda,$$

otherwise there is nothing to prove. This, together with Eqs. 19, 20 and 21 conclude the proof. $\qquad\square$

Now we prove an inequality involving the L^p norm of a function, the dyadic and the sharp maximal functions.

Theorem 5.5 *Let $0 < p_0 < +\infty$. Then, for all p such that $p_0 \leq p < +\infty$, there exists a constant N_p such that, for all f with $M_{\mathcal{D}}(f) \in L^{p_0}(m)$, we have*

(i) $\quad \|M_{\mathcal{D}}(f)\|_p \leq N_p \|M^{\#}(f)\|_p$;
(ii) $\quad \|f\|_p \leq N_p \|M^{\#}(f)\|_p$.

Proof To prove (i) it is possible to reply step by step [13, Th. 7.4.5.], so we omit the details. Inequality (ii) follows from (i) and the pointwise estimate $|f| \leq M_{\mathcal{D}}(f)$. $\qquad\square$

5.3 Complex Interpolation

We study the complex interpolation of $H^1(m)$, $BMO(m)$ and the $L^p(m)$ spaces.

Given two compatible normed spaces A_0 and A_1, for any $\theta \in (0, 1)$ we denote by $(A_0, A_1)_{[\theta]}$ the complex interpolation space obtained via Calderón's complex interpolation method (see [3] for the details). More precisely, we denote by Σ the strip $\{z \in \mathbb{C} : \Re z \in (0, 1)\}$ and denote by $\overline{\Sigma}$ its closure. We consider the class $\mathcal{F}(A_0, A_1)$ of all functions $F : \overline{\Sigma} \to A_0 + A_1$ such that the map $z \mapsto \langle F(z), \ell \rangle$ is continuous and bounded in $\overline{\Sigma}$ and analytic in Σ for every ℓ in the dual of $A_0 + A_1$, $F(it)$ is bounded on A_0 and $F(1 + it)$ is bounded on A_1 for every $t \in \mathbb{R}$. We endow $\mathcal{F}(A_0, A_1)$ with the norm

$$\|F\|_{\mathcal{F}} = \sup\{\max(\|F(it)\|_{A_0}, \|F(1 + it)\|_{A_1}) : t \in \mathbb{R}\}.$$

The space $(A_0, A_1)_{[\theta]}$ consists of all $f \in A_0 + A_1$ such that $f = F(\theta)$ for some $F \in \mathcal{F}(A_0, A_1)$ endowed with the norm

$$\|f\|_{[\theta]} = \inf\{\|F\|_{\mathcal{F}} : F \in \mathcal{F}(A_0, A_1), F(\theta) = f\}.$$

Theorem 5.6 *Suppose that $\theta \in (0, 1)$, $1 < q_1 < q < \infty$, $1 < p < p_1 < \infty$, $\frac{1}{q} = \frac{1-\theta}{q_1}$ and $\frac{1}{p} = 1 - \theta + \frac{\theta}{p_1}$. Then the following hold:*

(i) $\quad \left(L^{q_1}(m), BMO(m)\right)_{[\theta]} = L^q(m)$;
(ii) $\quad \left(H^1(m), L^{p_1}(m)\right)_{[\theta]} = L^p(m)$.

Proof We first prove (i). The inclusion $L^q(m) \subset \left(L^{q_1}(m), BMO(m)\right)_{[\theta]}$ follows from the fact that $L^{\infty}(m)$ is continuously included in $BMO(m)$ and $L^q(m) = \left(L^{q_1}(m), L^{\infty}(m)\right)_{[\theta]}$. To prove the reverse inclusion we consider any function $\phi : V \to \mathcal{R}$ which associates to every vertex $x \in V$ an admissible trapezoid R which contains x and any function $\eta : V \times V \to \mathbb{C}$ such that $|\eta(x, y)| = 1$ for every $(x, y) \in V \times V$. Define the linear operator

$S^{\phi,\eta}$ which on every function $f : V \to \mathbb{C}$ is defined as follows

$$S^{\phi,\eta} f(x) = \frac{1}{m(\phi(x))} \int_{\phi(x)} [f(y) - f_{\phi(x)}] \eta(x, y) dm(y), \qquad \forall x \in V.$$

Clearly,

$$|S^{\phi,\eta} f| \leq M^{\sharp}(f), \qquad \text{and} \qquad \sup_{\phi,\eta} |S^{\phi,\eta} f| = M^{\sharp}(f).$$

Given $f \in \left(L^{q_1}(m), BMO(m)\right)_{[\theta]}$ there exists $F \in \mathcal{F}(L^{q_1}(m), BMO(m))$ such that $F(\theta) = f$. For every $t \in \mathbb{R}$ we have

$$\|S^{\phi,\eta} F(it)\|_{q_1} \leq \|M^{\sharp}(F(it))\|_{q_1} \lesssim \|MF(it)\|_{q_1} \lesssim \|F(it)\|_{q_1},$$

where M is the Hardy–Littlewood maximal function associated with $\mathcal{R}$ which is bounded on $L^{q_1}(m)$. We also have that for every $t \in \mathbb{R}$

$$\|S^{\phi,\eta} F(1 + it)\|_{\infty} \leq \|M^{\sharp}(F(1 + it))\|_{\infty} \leq \|F(1 + it)\|_{BMO}.$$

It follows that $S^{\phi,\eta} F \in \mathcal{F}(L^{q_1}(m), BMO(m))$ and $\|S^{\phi,\eta} F\|_{\mathcal{F}} \lesssim \|F\|_{\mathcal{F}}$. Hence

$$\|S^{\phi,\eta} F(\theta)\|_q \lesssim \|F(\theta)\|_{(L^{q_1}(m), BMO(m))_{[\theta]}} = \|f\|_{(L^{q_1}(m), BMO(m))_{[\theta]}}.$$

By taking the supremum over all ϕ and η and applying Theorem 5.5 we get

$$\|f\|_q \lesssim \|M^{\sharp}(f)\|_q \lesssim \|f\|_{(L^{q_1}(m), BMO(m))_{[\theta]}}.$$

This proves the inclusion $\left(L^{q_1}(m), BMO(m)\right)_{[\theta]} \subset L^p(m)$ and concludes the proof of (*i*). The proof of (*ii*) follows by the duality between $H^1(m)$ and $BMO(m)$ and [3, Cor. 4.5.2]. □

Theorem 5.7 *Suppose that $\theta \in (0, 1)$, $\frac{1}{q} = 1 - \theta$. Then the following hold:*

(*i*) $\left(L^1(m), BMO(m)\right)_{[\theta]} = L^q(m)$;

(*ii*) $\left(H^1(m), L^{\infty}(m)\right)_{[\theta]} = L^q(m)$;

(*iii*) $\left(H^1(m), BMO(m)\right)_{[\theta]} = L^q(m)$.

Proof Take $r \in (1, q)$ and $\phi \in (0, 1)$ such that $\frac{1}{r} = 1 - \phi + \frac{\phi}{q}$. Then $\left(L^1(m), L^q(m)\right)_{[\phi]} = L^r(m)$. Moreover, by Theorem 5.6,

$$\left(L^r(m), BMO(m)\right)_{[\gamma]} = L^q(m)$$

if $\frac{1}{q} = \frac{1-\gamma}{r}$. Since $L^1(m) \cap BMO(m)$ contains the space of compactly supported functions, it is dense in $L^r(m)$ and $L^q(m)$. Then, by the reiteration theorem [28, Th. 2], we deduce that $\left(L^1(m), BMO(m)\right)_{[\theta]} = L^q(m)$.

Take $r \in (1, q)$ and $\phi \in (0, 1)$ such that $\frac{1}{r} = 1 - \phi + \frac{\phi}{q}$. Then by Theorem 5.6, $\left(H^1(m), L^q(m)\right)_{[\phi]} = L^r(m)$. Moreover, $\left(L^r(m), L^{\infty}(m)\right)_{[\gamma]} = L^q(m)$. The space of compactly supported functions with vanishing integral is contained in $H^1(m) \cap L^{\infty}(m)$ and is dense in $L^r(m)$ and $L^q(m)$. Then by the reiteration theorem [28, Th. 2], we deduce that $\left(H^1(m), L^{\infty}(m)\right)_{[\theta]} = L^q(m)$. Property (*iii*) follows from (*i*) and (*ii*) and the fact that $H^1(m) \subset L^1(m)$ and $L^{\infty}(m) \subset BMO(m)$. □

5.4 Integral Operators

We now prove that integral operators which satisfy a Hörmander's condition are bounded from $H^1(m)$ to $L^1(m)$ and from $L^\infty(m)$ to $BMO(m)$.

Theorem 5.8 *Let T be a linear operator which is bounded on $L^2(m)$ and admits a kernel K.*

(i)   Assume K satisfies the condition

$$\sup_{R \in \mathcal{R}} \sup_{y,z \in R} \int_{(R^*)^c} |K(x, y) - K(x, z)| \, dm(x) < +\infty, \tag{22}$$

where, for any $R = R_{h'}^{h''}(x) \in \mathcal{R}$, we define $R^* = \{x \in V : d(x, R) < h'\}$. Then T extends to a bounded operator from $H^1(m)$ to $L^1(m)$ and on $L^p(m)$, for $1 < p < 2$.

(ii)   If K satisfies the condition

$$\sup_{R \in \mathcal{R}} \sup_{y,z \in R} \int_{(R^*)^c} |K(y, x) - K(z, x)| \, dm(x) < +\infty, \tag{23}$$

where R^* is defined as in (i), then T extends to a bounded operator from $L^\infty(m)$ to $BMO(m)$ and on $L^q(m)$, for $2 < q < +\infty$.

Proof We first observe that given $R = R_{h'}^{h''}(x) \in \mathcal{R}$, we have $m(R^*) = (h''+h'-1)m(x) \leq 3m(R)$. Thus we can follow verbatim [2, Th. 3] and conclude that, if K satisfies Eq. 22, then T is bounded from $H^1(m)$ to $L^1(m)$. By Theorem 5.2, it follows that T is bounded on $L^p(m)$, for $1 < p < 2$. Suppose that K satisfies Eq. 23. Then the kernel K^* of the adjoint operator T^* satisfies Eq. 22. By (i), T^* extends to a bounded operator from $H^1(m)$ to $L^1(m)$ and on $L^p(m)$, for $1 < p < 2$. By duality it follows that T extends to a bounded operator from $L^\infty(m)$ to $BMO(m)$ and on $L^q(m)$, for $2 < q < +\infty$.   □

Remark 5.9 Theorem 5.8 applies to suitable spectral multipliers and to first order Riesz transforms associated with a distinguished Laplacian on the homogeneous tree (see [14, Th. 2.3] and [2]). We are currently studying the boundedness properties of spectral multipliers and Riesz transforms on more general trees and for more general Laplacians which are self-adjoint with respect to a flow measure. This is work in progress.
