**Abstract:** In this study, a set of  $\text{CuCeO}_x$  catalysts was prepared via the coprecipitation method using a Multi-Inlet Vortex Reactor: the Cu wt.% content is 5, 10, 20, 30 and 60. Moreover, pure  $\text{CeO}_2$  and  $\text{CuO}$  were synthesized for comparison purposes. The physico-chemical properties of this set of samples were investigated by complementary techniques, e.g., XRD,  $\text{N}_2$  physisorption at  $-196^\circ\text{C}$ , Scanning Electron Microscopy, XPS, FT-IR, Raman spectroscopy and  $\text{H}_2$ -TPR. Then, the  $\text{CuCeO}_x$  catalysts were tested for the CO and ethene oxidation reactions. As a whole, all the prepared samples presented good catalytic performances towards the CO oxidation reaction (1000 ppm CO, 10 vol.%  $\text{O}_2/\text{N}_2$ ): the most promising catalyst was the 20% $\text{CuCeO}_x$  (complete CO conversion at  $125^\circ\text{C}$ ), which exhibited a long-term thermal stability. Similarly, the oxidative activity of the catalysts were evaluated using a gaseous mixture containing 500 ppm  $\text{C}_2\text{H}_4$ , 10 vol.%  $\text{O}_2/\text{N}_2$ . Accordingly, for the ethene oxidation reaction, the 20% $\text{CuCeO}_x$  catalyst evidenced the best catalytic properties. The elevated catalytic activity towards CO and ethene oxidation was mainly ascribed to synergistic interactions between  $\text{CeO}_2$  and  $\text{CuO}$  phases, as well as to the high amount of surface-chemisorbed oxygen species and structural defects.

**Keywords:** CO oxidation; ethene oxidation; copper-cerium mixed oxides; Multi-Inlet Vortex Reactor; synergistic effects

## 1. Introduction

Over the last few years, the emission limits in the automotive field have become stricter. Several pollutants are produced in diesel and gasoline engines, such as carbon monoxide (CO) volatile organic compounds (VOCs), nitrogen oxides ( $\text{NO}$ ,  $\text{N}_2\text{O}$  and  $\text{NO}_2$ , labelled as  $\text{NO}_x$ ), unburned carbon-based compound (UHC) and particulate matter (PM) [1–4].

Carbon monoxide (CO) originates from the incomplete combustion of fuel inside the engine reaction chamber. The engine working conditions are directly connected with the CO production: a higher quantity of CO is generated when the air-to-fuel ratio is under-stoichiometric ( $\lambda$  ratio  $< 1$ , rich mixture) [4,5]. However, it is possible to form CO in lean conditions too ( $\lambda$  ratio  $> 1$ ), due to kinetic effects [6]. The CO is a harmful substance for humans because it can create confusion and asphyxia over a certain concentration [7–9].

The volatile organic compounds (VOCs) are a set of various substances present in the atmosphere that are originated due to natural or human-related processes (i.e., biogenic or anthropogenic, respectively) [10]. These compounds may represent an important risk for humans' health [11]. Moreover, they can participate in atmospheric photochemical processes that lead to the formation of other harmful substances (e.g., peroxyacyl nitrates or ozone) [11,12]. Accordingly, the emission of these substances, as well as the emission

of CO, is regulated [13]. In previous research works [14], ethene has been often used as VOC probe molecule [15–20]. In this sense, ethene has shown higher resistance to oxidation respect to other VOCs (e.g., propylene) [16,18], whereas it can be oxidized at temperatures similar to those required by some aromatic compounds, e.g., toluene [16,20].

The catalytic systems used for the abatement of automotive pollutants typically contain noble metals. Among them, Pt is probably the most used metal, since it is very active towards several oxidation reactions [21–27]. However, there are limitations in the utilization of noble metals (i.e., their high cost and the poisoning phenomenon) [28]. In this work, Cu was chosen in order to enhance the ceria reactivity and to be proposed as a valid alternative to noble metal-based catalysts.

According to the literature, CeO<sub>2</sub>-based catalysts are interesting materials for both the CO and ethene oxidations [17,18,29–36]. Ceria exhibits good redox properties due to the presence of the Ce<sup>3+</sup>–Ce<sup>4+</sup> couple and it is able to store a high amount of oxygen. Moreover, the addition of foreign metals inside the CeO<sub>2</sub> framework allows to further improve its promising performances [37–45].

Among the foreign metals, Cu is of particular interest. In fact, copper can be found as Cu<sup>+</sup> and Cu<sup>2+</sup>, which could create a synergistic effect in terms of coupled Ce and Cu redox pairs (i.e., Ce<sup>3+</sup>–Ce<sup>4+</sup> and Cu<sup>2+</sup>–Cu<sup>+</sup>) during the oxidation reactions. Specifically, the presence of CuO enhances the redox mechanism at the catalysts surface, because CuO and CeO<sub>2</sub> can be reduced and oxidized at the same time [46–48]. Moreover, copper provides new active sites for the adsorption of reduced molecules. Hence, CuO–CeO<sub>2</sub> systems are highly effective for both the CO and ethene oxidation reactions [14,17,18,49–51].

In this work, a set of CuCeO<sub>x</sub> catalysts was studied for the catalytic oxidation of CO and ethene. The latter was used as probe molecule for the oxidation of VOCs. The samples were also characterized by complementary techniques, such as X-Ray Diffraction (XRD), N<sub>2</sub> physisorption at –196 °C, Field Emission Scanning Electron Microscopy (FESEM), X-ray Photoelectron Spectroscopy (XPS), Fourier Transform Infra-Red spectroscopy (FT-IR), Raman spectroscopy and H<sub>2</sub> Temperature-Programmed Reduction (H<sub>2</sub>-TPR) in order to unveil which physico-chemical properties determine the catalytic activity.

## 2. Materials and Methods

### 2.1. Synthesis of CuCeO<sub>x</sub> Catalysts

A Multi-Inlet Vortex Reactor (MIVR) was used to synthesize the CuCeO<sub>x</sub> catalysts. Five samples were prepared with different Cu wt.% content, namely 5, 10, 20, 30 and 60, and herein labeled as 5%CuCeO<sub>x</sub>, 10%CuCeO<sub>x</sub>, 20%CuCeO<sub>x</sub>, 30%CuCeO<sub>x</sub> and 60%CuCeO<sub>x</sub>, respectively. Moreover, pure CeO<sub>2</sub> and CuO were prepared for comparison purposes. The synthesis procedure was adapted from reference [52].

Two 60 mL syringes were filled with a 0.1 M NaOH (Merk, Steinheim, Germany). Afterwards, a metal precursor solution (0.1 M) at the desired weight ratio was prepared with Ce(NO<sub>3</sub>)<sub>3</sub>•6H<sub>2</sub>O and Cu(NO<sub>3</sub>)<sub>2</sub>•3H<sub>2</sub>O (Merck, Steinheim, Germany). The metal precursor solution was put inside other two syringes (60 mL). Then, the four syringes were connected to the MIVR inlets (Ø<sub>inlet</sub> = 1 mm), as shown in Scheme 1A and 1B. The syringes are driven by a KD Scientific KDS220 infusion syringe pump (Merck, Steinheim, Germany) with the total flow rate fixed to 20 mL min<sup>–1</sup> in order to have a turbulent flow in the MIVR reaction chamber (Ø<sub>reaction chamber</sub> = 4 mm), according to previous fluid dynamic studies (Re = 8320) [52,53]. During the injection, the metal hydroxides nanoparticles (CuCeOH NPs) were formed in the reaction chamber, meanwhile the suspension was moving upward in a spiral way towards the outlet on the top of the reactor. Then, the suspension was collected into a beaker (Scheme 1C).

Afterwards, the thus-obtained suspension was stirred for 1 h at room temperature. Then, it was centrifuged (5000 rpm, 1 h) and the produced powder was washed three times with ultra-pure water (MilliQ, Direct Water Purification System, Merck, Steinheim, Germany). Finally, the powder was dried overnight at 60 °C and calcined at 650 °C for 4 h (heating rate of 10 °C min<sup>–1</sup>).

## 2.2. Characterization Techniques

The X-ray diffraction (XRD) patterns of the powders were registered by means of an X'Pert Philips PW3040 diffractometer (Malvern Panalytical Ltd., Malvern, UK) and using Cu K $\alpha$  radiation ( $2\theta = 10\text{--}80^\circ$ ; step =  $0.013^\circ$   $2\theta$ ; time per step = 0.2 s). The data obtained was indexed using the Powder Data File database (PDF-2 1999, International Centre of Diffraction Data).

The measurement of the textural properties of the catalysts (i.e., specific surface area and total pore volume) was carried out by performing N<sub>2</sub> physisorption at  $-196^\circ\text{C}$  in a Micromeritics Tristar II 3020 (v1.03, Micromeritics Instrument Corp., Norcross, GA, USA). Before the analysis, the samples were outgassed at  $200^\circ\text{C}$  for 2 h. The values of specific surface area (SSA) were calculated through the Brunauer–Emmett–Teller (BET) method. On the other hand, the pore volume ( $V_p$ ) was assessed by analyzing the desorption phase using the Barrett–Joyner–Halenda (BJH) method.

The morphology of the catalysts was investigated with a field emission scanning electron microscope (FESEM Zeiss MERLIN, Gemini-II column, Oberkochen, Germany), in which Energy Dispersive X-Ray (EDX) analysis was performed as well.

The elemental composition of the samples was also investigated using an Inductively Coupled Plasma Mass Spectrometer (iCAP Q ICP-MS, ThermoFisher Scientific, Waltham, MA, USA). For this analysis, 100 mg of each sample were dissolved in an aqueous solution of hydrochloric acid (1 M), nitric acid (1 M) and ascorbic acid (0.5 M), which was then stirred for 8 h to completely solubilize the powder.

Raman spectroscopy was carried out with a Renishaw InVia micro-Raman spectrometer (Renishaw plc, Wotton-under-Edge, UK). The spectra were collected at room temperature using a 514.5 nm excitation wavelength, a 10 mW laser power, a  $5\times$  objective and a 225 s total acquisition time. For each sample, three spectra were collected in different points and averaged. The ratio between the area of the defect-related band (D band) and that of the ceria F<sub>2g</sub> peak ( $D/F_{2g}$  ratio) was calculated as an estimation of defect abundance. The areas were obtained by deconvolution of the main bands using Lorentzian fitting curves.

FT-IR (Fourier transform infrared) spectroscopy was performed using a Bruker Invenio S spectrophotometer (Bruker Corporation, Billerica, MA, USA) equipped with a cooled MCT detector. Self-supporting wafers were prepared by pressing the catalyst powder and were analyzed in transmission mode in a quartz cell equipped with KBr windows. Prior to analysis, the wafers were outgassed at 50 or  $150^\circ\text{C}$  for 1 h to remove water, using a standard vacuum frame. The spectra were collected at a  $2\text{ cm}^{-1}$  resolution and were normalized to the mass per unit area of each wafer.

The core-level spectra of the elements of interest were studied through the X-ray photoelectron spectroscopy (XPS) technique. The analyses were performed in a PHI Versa probe apparatus (Physical Electronics Inc. PHI, Chanhassen, MN, USA) using: band-pass energy: 187.85 eV; take-off angle:  $45^\circ$ ; X-ray spot size diameter: 100  $\mu\text{m}$ .

The reducibility of the catalysts was investigated performing temperature-programmed reduction analyses under a flow of H<sub>2</sub> (H<sub>2</sub>-TPR). The analyses were carried out in a Ther-

moQuest TPD/R/O 1100 (ThermoFisher Scientific, Milan, Italy), comprising a thermal conductivity detector (TCD). Before the analysis, an oxidative pretreatment was carried out under a flow of  $O_2$  ( $20\text{ mL min}^{-1}$ ) at  $550\text{ }^\circ\text{C}$  for 1 h. Subsequently, the catalysts were put under a reducing gas mixture containing 5 vol.% of  $H_2/Ar$  (flowrate:  $20\text{ mL min}^{-1}$ ). During a typical analysis, the temperature was increased from  $50\text{ }^\circ\text{C}$  until  $900\text{ }^\circ\text{C}$  (heating rate  $10\text{ }^\circ\text{C min}^{-1}$ ). At the end of the analysis, the temperature was held at  $900\text{ }^\circ\text{C}$  for 10 min. For the  $H_2$ -TPR analysis, the onset temperature ( $T_{\text{onset}}$ ) was considered as a catalytic parameter. The  $T_{\text{onset}}$  is defined as the intersection of the tangent passing through the inflection point of the first reduction peak and the baseline.

### 2.3. Catalytic Activity Tests

The catalytic activity of the prepared powder catalysts was performed in a temperature-programmed oxidation (TPO) setup comprising a PID-controlled furnace. A quartz U-tube reactor (ID = 0.4 cm) hosted a fixed-bed containing the catalyst. The temperature was quantified using a K-type thermocouple set in the upper limit of the fixed-bed. The gas outlet from the reactor was analyzed by a non-dispersive infrared analyzer ABB Uras 14 (ABB S.p.A – PAMA, Milan, Italy).

#### 2.3.1. CO Oxidation Reaction

The catalytic bed for the CO oxidation reaction was prepared by putting 100 mg of catalyst inside a quartz-U reactor. Then, the catalyst was pretreated with  $50\text{ mL min}^{-1}$  of  $N_2$  for 30 min at  $100\text{ }^\circ\text{C}$ , in order to desorb impurities on the catalyst surface (i.e.,  $H_2O$ ). Then, the temperature was cooled down until  $25\text{ }^\circ\text{C}$ . After that, a gas mixture containing about 1000 ppm CO and 10 vol.%  $O_2$  balanced with  $N_2$  was sent to the reactor (total flow  $50\text{ mL min}^{-1}$ ). Then, the temperature was increased by  $25\text{ }^\circ\text{C}$  (heating rate  $5\text{ }^\circ\text{C min}^{-1}$ ). The temperature was kept constant for 30 min in order to have a complete stabilization at each increment of the temperature and to avoid adsorption-desorption phenomena. The test finished when the CO conversion reached the 100%.

#### 2.3.2. Ethene Oxidation Reaction

For the ethene catalytic oxidation tests, 100 mg of catalyst were introduced into the quartz-U reactor. Prior to the catalytic testing, a degassing pretreatment under a flow of  $N_2$  ( $50\text{ mL min}^{-1}$ ) at  $150\text{ }^\circ\text{C}$  was performed for 1 h. Afterwards, the temperature was set to  $100\text{ }^\circ\text{C}$  and the catalytic test started. During this test, a gaseous mix containing  $C_2H_4$  (500 ppm),  $O_2$  (10 vol.%) and  $N_2$  (balance) was flowed ( $50\text{ mL min}^{-1}$ ) in the reactor. In addition, the temperature was raised from  $100\text{ }^\circ\text{C}$  to  $425\text{ }^\circ\text{C}$ . Isothermal steps were performed every  $25\text{ }^\circ\text{C}$  until the conversion of the ethene (in terms of outlet CO and  $CO_2$  concentrations) was stable.

## 3. Results

### 3.1. Structural and Textural Properties

The crystalline structure of the prepared samples was investigated by means of XRD analysis in the  $10^\circ < 2\theta < 80^\circ$  range. The diffractograms of the catalysts are reported in Figure 1. As a whole, all the samples (except for CuO) exhibit the typical  $CeO_2$  cubic fluorite structure, characterized by the (1 1 1), (2 0 0), (2 2 0), (3 1 1), (2 2 2), (4 0 0), (3 3 1) and (4 2 0)-type planes [31,33,37,54,55]. The patterns of these samples were compared to reference code 96-900-9009 ( $CeO_2$ ). The CuO (reference code 96-101-1195) has the main diffraction peaks at  $35.6^\circ$  ((0 2 2)-type plane) and  $38.8^\circ$  ((1 1 1)-type plane), which are ascribed to the typical monoclinic crystalline phase of CuO [56].

Notably, the samples  $30\%CuCeO_x$  and  $60\%CuCeO_x$  exhibit both CuO and  $CeO_2$  patterns. This outcome evidences the presence of two different phases (segregates). Furthermore, the presence of weak reflection peaks of the CuO was detected for  $10\%CuCeO_x$  and  $20\%CuCeO_x$  too (Figure S1).

**Figure 1.** X-ray diffractograms in the range  $10^\circ < 2\theta < 80^\circ$  over the samples. The typical peaks of CuO are marked with asterisks.

The crystallites dimensions ( $D_c$ ) were evaluated by Scherrer's equation and reported in Table 1. As a whole, all the samples have  $\text{CeO}_2$  crystallites with similar dimensions, in the range between 10 and 16 nm. Instead, the crystal size of the CuO phase gradually increases with the Cu content, from 7 nm (10%CuCeO<sub>x</sub>) to 73 nm (pure CuO).

**Table 1.** Textural properties of the CuCeO<sub>x</sub> catalysts derived by means of X-ray diffraction, N<sub>2</sub> physisorption and Raman spectroscopy.

Catalyst	$D_c^a$ (nm)		SSA <sup>b</sup> (m <sup>2</sup> g <sup>−1</sup> )	$V_p^c$ (cm <sup>3</sup> g <sup>−1</sup> )	D/F <sub>2g</sub> <sup>d</sup>
	CeO <sub>2</sub>	CuO			
CeO <sub>2</sub>	15	-	45	0.07	0.06
5%CuCeO <sub>x</sub>	13	-	50	0.08	0.13
10%CuCeO <sub>x</sub>	11	7	55	0.10	0.16
20%CuCeO <sub>x</sub>	10	9	50	0.09	0.34
30%CuCeO <sub>x</sub>	14	26	22	0.03	0.13
60%CuCeO <sub>x</sub>	16	39	11	0.06	0.09
CuO	-	73	2	0.01	-

<sup>a</sup> Crystallite size estimated by the Scherrer's equation; <sup>b</sup> Specific surface area calculated by the Brunauer–Emmett–Teller (BET) method; <sup>c</sup> Total pore volume evaluated by the Barrett–Joyner–Halenda (BJH) method; <sup>d</sup> Ratio between the area of the defect band and that of the F<sub>2g</sub> peak in the Raman spectra.

The SSA and the total pore volume were investigated through the N<sub>2</sub> physisorption analysis at  $-196^\circ\text{C}$ . The results are resumed in Table 1. The 10%CuCeO<sub>x</sub> presents the highest SSA (55 m<sup>2</sup> g<sup>−1</sup>,  $V_p = 0.10\text{ cm}^3\text{ g}^{-1}$ ), while the 5%CuCeO<sub>x</sub> and 20%CuCeO<sub>x</sub> have promising textural properties as well (SSA = 50 m<sup>2</sup> g<sup>−1</sup>,  $V_p = 0.08\text{--}0.09\text{ cm}^3\text{ g}^{-1}$ ).

The morphology of the CuCeO<sub>x</sub> catalysts was investigated by means of FESEM analysis and the micrographs are reported in Figure 2. The CeO<sub>2</sub>, 5%CuCeO<sub>x</sub>, 10%CuCeO<sub>x</sub> and 20%CuCeO<sub>x</sub> images suggest a good homogeneity of the particle size. Conversely, at higher Cu content, namely, 30 and 60 wt.%, big CuO particles were observed along with small

CeO<sub>2</sub> nanoparticles. The CuO phase in 30%CuCeO<sub>x</sub> and 60%CuCeO<sub>x</sub> presents the typical octahedral or truncated-octahedral shape, confirmed by other research works [56,57].

**Figure 2.** FESEM images of the CuCeO<sub>x</sub> catalysts.

The elemental composition of the different catalysts was evaluated through EDX and ICP analyses (Tables 2 and S1): for all the samples, both the techniques confirmed a copper content similar to the nominal one.

Figure 3A displays the Raman spectra of the different catalysts. Raman spectroscopy can indeed provide insight into the modifications induced in the catalyst structure and defectiveness by the increasing content of Cu. Pure ceria features an intense F<sub>2g</sub> peak at 464 cm<sup>−1</sup> related to the symmetric stretching of Ce–O bonds in the fluorite lattice [58]. A much less intense band at about 595 cm<sup>−1</sup> (D band) is instead associated with the presence

of defects and it is usually assigned to intrinsic Frenkel sites, in which a vacancy is generated by the displacement of an oxygen atom into an interstitial position [58,59].

**Table 2.** EDX and ICP analysis of the  $\text{CuCeO}_x$  catalysts: the elemental content is expressed in percentage of Ce and Cu with respect to the total amount of cations (Ce + Cu).

Catalyst	Elemental Composition (wt.%)					
	EDX *			ICP		
	Ce	Cu	Tot.	Ce	Cu	Tot.
5%CuCeO <sub>x</sub>	97	3	100	97	3	100
10%CuCeO <sub>x</sub>	92	8	100	90	10	100
20%CuCeO <sub>x</sub>	82	18	100	79	21	100
30%CuCeO <sub>x</sub>	67	33	100	67	33	100
60%CuCeO <sub>x</sub>	32	68	100	37	63	100

\* The values are estimated over three different areas.

**Figure 3.** (A) Raman spectra of (a)  $\text{CeO}_2$ , (b) 5%CuCeO<sub>x</sub>, (c) 10%CuCeO<sub>x</sub>, (d) 20%CuCeO<sub>x</sub>, (e) 30%CuCeO<sub>x</sub>, (f) 60%CuCeO<sub>x</sub> and (g) CuO collected at ambient conditions, normalized to the intensity of ceria  $F_{2g}$  peak. (B) Variation of the D/ $F_{2g}$  ratio as a function of the Cu content.

The ceria-copper mixed oxides are characterized by analogous Raman spectra, although some differences are evident. The  $F_{2g}$  peak of doped ceria is broader and red-shifted to  $448\text{--}451\text{ cm}^{-1}$ , evidencing structural distortion [60,61]. Moreover, the intensity of the defect band gradually increases upon copper addition and new defect-related components appear. In detail, a peak centered at  $620\text{--}630\text{ cm}^{-1}$  can be ascribed to substitutional sites containing a copper atom in 8-fold coordination [62,63], while a shoulder band around  $550\text{ cm}^{-1}$  arises as a consequence of oxygen vacancies generation [64–66]. These outcomes point out that copper is partially incorporated in ceria structure, causing lattice distortion and the formation of new extrinsic defects. At high Cu loading, the typical peaks of CuO starts to be visible in the Raman spectra of the mixed catalysts, as a consequence of the segregation of this oxide. These components, centered at about  $280$ ,  $335$  and  $612\text{ cm}^{-1}$ , have been ascribed to one  $A_g$  and two  $B_g$  modes, respectively [67].

Spectral deconvolution allowed to estimate the abundance of defects in the cerium oxide structure, by calculating the ratio between the area of the defect (D) band and the area of the  $F_{2g}$  peak of ceria ( $D/F_{2g}$ ) [63,68]. For highly doped ceria, a peak was set at  $612\text{ cm}^{-1}$  in order to take into account the presence of segregated CuO, and its contribution was not considered in the calculation of the D band area. The  $D/F_{2g}$  values are reported in Table 1 and their trend is depicted in Figure 3B. The amount of defects initially grows with increasing Cu doping and it is maximum for the 20%CuCeO<sub>x</sub> sample. However, further addition of copper results in the segregation of CuO particles rather than in the formation of structural defects in the ceria framework, in line with previous studies [17].

FT-IR spectroscopy was employed for studying the chemical species at the surface of the different catalysts. FT-IR spectra collected after outgassing the samples at  $150\text{ }^{\circ}\text{C}$  are reported in Figure 4. The thermal treatment allows to remove physisorbed water and to more clearly detect the vibrational modes of the surface species (for comparison purposes, spectra of samples outgassed at  $50\text{ }^{\circ}\text{C}$  are displayed in Figure S2).

**Figure 4.** Normalized FT-IR spectra of the different catalysts outgassed at  $150\text{ }^{\circ}\text{C}$  in the (A)  $3800\text{--}3000\text{ cm}^{-1}$  and (B)  $2000\text{--}800\text{ cm}^{-1}$  range.

The bands in the  $3800\text{--}3000\text{ cm}^{-1}$  region are related to the stretching of the hydroxyl groups. Different OH species are present at the surface of the ceria-rich materials: the band at  $3710\text{ cm}^{-1}$  can be ascribed to isolated OH groups while the intense peak at  $3655\text{--}3650\text{ cm}^{-1}$  was assigned to bridging OH [69,70]. The asymmetry of the latter component has been previously attributed to the presence of bridging OH in the proximity of an oxygen vacancy, giving rise to a shoulder at  $3640\text{--}3630\text{ cm}^{-1}$  [69]. The less intense band at about  $3520\text{ cm}^{-1}$  may instead be related to triply coordinated OH [69,70]. The presence of a variegated population of OH groups is an index of ceria hydrophilicity. According to previous studies,

a hydrophilic support can promote the catalytic activity of metallic active sites [71]. All the hydroxyl species become less abundant at high copper loading and are no more detectable in pure copper oxide, suggesting that Cu doping can reduce ceria hydrophilicity.

The 1700–800  $\text{cm}^{-1}$  region is featured by several broad bands which signal the presence of a heterogeneous population of carbonate and formate species, including monodentate, bidentate, bridged and polydentate carbonates [58,70,72,73]. The carbonate fingerprint is quite similar for pure ceria and for the mixed oxides containing up to 30% of copper. Conversely, new components can be noticed in the FT-IR spectrum of the 60%CuCeO<sub>x</sub> sample, probably linked to carbonate species at the surface of CuO particles. An almost flat profile was obtained for pure copper oxide, likely due to the much lower specific surface area of this material (see BET analysis in Table 1).

### 3.2. Chemical Properties

#### 3.2.1. Surface Oxidation States

The oxidation state of the elements of interest and the surface species of the catalysts were investigated through XPS measurements. The Ce 3*d*, O 1*s* and Cu 2*p* spectra are reported in Figure 5, while the Cu LMM Auger spectra are shown in Figure S3.

**Figure 5.** XP spectra of (a) CeO<sub>2</sub>, (b) 5%CuCeO<sub>x</sub>, (c) 10%CuCeO<sub>x</sub>, (d) 20%CuCeO<sub>x</sub>, (e) 30%CuCeO<sub>x</sub>, (f) 60%CuCeO<sub>x</sub> and (g) CuO in the (A) Ce 3*d*, (B) O 1*s* and (C) Cu 2*p* regions.

The Ce 3*d* core levels are reported in Figure 5A, which shows the different *u* and *v* peaks corresponding to 3*d*<sub>3/2</sub> and 3*d*<sub>5/2</sub> spin orbital, respectively. The Ce<sup>3+</sup> amount was estimated by the deconvolution of the *u*<sub>1</sub> and *v*<sub>1</sub> peaks, while the amount of Ce<sup>4+</sup> was evaluated by the deconvolution of *u*<sub>0</sub>, *v*<sub>0</sub>, *u*<sub>2</sub>, *v*<sub>2</sub>, *u*<sub>3</sub> and *v*<sub>3</sub> peaks [17,18,31]. The relative

amounts of  $\text{Ce}^{3+}$  and  $\text{Ce}^{4+}$  are reported in Table 3. The 10%CuCeO<sub>x</sub> and 20%CuCeO<sub>x</sub> samples exhibit the highest  $\text{Ce}^{3+}$  amount, namely 25 and 26 at.%, respectively.

**Table 3.** Relative amount of Ce species as derived from XP spectra of Ce 3d core level.

Catalyst	$\text{Ce}^{3+}$ (at.%)	$\text{Ce}^{4+}$ (at.%)
CeO <sub>2</sub>	12	88
5%CuCeO <sub>x</sub>	22	78
10%CuCeO <sub>x</sub>	25	75
20%CuCeO <sub>x</sub>	26	74
30%CuCeO <sub>x</sub>	19	81
60%CuCeO <sub>x</sub>	21	79

The O 1s core levels are displayed in Figure 5B. Each O 1s spectrum is characterized by two peaks: the one at higher binding energy (BE) which is related to chemisorbed oxygen, O<sub>α</sub> (O<sub>2</sub><sup>2−</sup>, carbonates, O<sup>−</sup> or OH<sup>−</sup>), while the one at lower binding energy is due to lattice oxygen, O<sub>β</sub> (O<sup>2−</sup> of the Ce-O bonds) [17,31,54,74,75]. The relative abundance of the O<sub>α</sub> and O<sub>β</sub> species is reported in Table 4. Interestingly, when the Cu content increases, two different O<sub>β</sub> species can be noticed, due to the simultaneous presence of two different oxides, CeO<sub>2</sub> and CuO. This is clearly evident for the 30%CuCeO<sub>x</sub> and 60%CuCeO<sub>x</sub> samples (Figure 5B, curves e and f): the two O<sub>β</sub> peaks can be ascribed to Cu-O (529.6–529.9 eV) and Ce-O (528.7–528.8 eV). Moreover, when the Cu content increases, the O<sub>β</sub> peak generally becomes more intense [74–78]. Furthermore, the O<sub>α</sub>-to-O<sub>β</sub> ratio was calculated and reported in Table 4. Interestingly, the 20%CuCeO<sub>x</sub> sample exhibits the highest ratio, namely, 0.67, possibly due to the higher content of structural defects (vide Raman) [79]. The presence of abundant O<sub>α</sub> may enhance the reactivity during the oxidation reactions since these oxygen species, namely, O<sub>2</sub><sup>2−</sup>, carbonates, O<sup>−</sup> or OH<sup>−</sup>, are more reactive compared to bulk oxygen [17,54,74,75].

**Table 4.** Relative amounts of the surface-adsorbed oxygen (O<sub>α</sub>) and lattice oxygen (O<sub>β</sub>) species and their respective ratios, as derived from the deconvolution of the O 1s core level.

Catalyst	O <sub>α</sub>		O <sub>β</sub> (Cu-O)		O <sub>β</sub> (Ce-O)		O <sub>α</sub> /O <sub>β</sub>
	BE (eV)	%-Atom	BE (eV)	%-Atom	BE (eV)	%-Atom	
CeO <sub>2</sub>	531.2	26	-	-	529.0	74	0.35
5%CuCeO <sub>x</sub>	530.9	32	-	-	529.1	68	0.47
10%CuCeO <sub>x</sub>	531.4	33	-	-	529.4	67	0.49
20%CuCeO <sub>x</sub>	531.3	40	-	-	529.3	60	0.67
30%CuCeO <sub>x</sub>	531.4	31	529.9	36	528.8	33	0.45
60%CuCeO <sub>x</sub>	531.3	29	529.6	45	528.7	26	0.41
CuO	531.4	43	529.8	57	-	-	0.75

The Cu 2p spectra are reported in Figure 5C. The most intense peak can be deconvoluted into two different Cu<sup>2+</sup> species: the peak at lower binding energy is related to Cu-O bonds in the lattice, while Cu-CO<sub>3</sub> or Cu-(OH)<sub>2</sub> species bonded at the surface give a contribution at higher binding energy. The Cu LMM Auger spectra are reported in Figure S3. The Auger peaks are centered in the range 917.0–917.7 eV, thus confirming the presence of Cu<sup>2+</sup> species in the CuO phase and the absence of Cu metallic phase which could be ascribed to the presence of possible alloy [74,77,78].

### 3.2.2. Reducibility Tests

The H<sub>2</sub>-TPR measurement was performed in order to investigate the reducibility of the CuCeO<sub>x</sub> catalysts and the obtained profiles are reported in Figure 6A. Pure ceria is characterized by a side peak in the 300–400 °C range which can be attributed to the reduction of chemisorbed oxygen species (i.e., carbonates) that are feebly attached to the catalyst surface [80–82]. Furthermore, a main reduction peak is centered at 540 °C and it is due to the reduction of surface Ce<sup>4+</sup> species [17,18,54,83]. Finally, the signal occurring at higher temperatures (T > 600 °C) can be attributed to the reduction of Ce<sup>4+</sup> in the bulk [17,18,54,80–83].

**Figure 6.** (A) H<sub>2</sub>-TPR profiles of the CuCeO<sub>x</sub> catalysts. (B) Trend in the position of the low-temperature reduction peaks as a function of the Cu content in the different samples.

The samples containing a Cu loading between 5 and 60 wt.% exhibit two convoluted reduction peaks in the 150–500 °C range, as shown in Figure 6A. As a whole, the reduction of these CuCeO<sub>x</sub> catalysts occurs at lower temperatures comparing with pure CeO<sub>2</sub>. Thus, the reducibility of these samples was enhanced by the presence of CuO alongside CeO<sub>2</sub> phase.

According to the literature, the first low temperature peak was attributed to the reduction of Ce-O-Cu species, while the second one was assigned to the reduction of small CuO clusters interacting with CeO<sub>2</sub> [17,18,34,74,80,83,84]. Moreover, when the copper loading increases, the second peak shifts towards higher temperatures and this phenomenon may be related to the larger CuO particles. Figure 6B displays the trend of the position of the T<sub>onset</sub> reduction peaks as a function of the Cu content. The following trend for the surface reducibility can be outlined: 10%CuCeO<sub>x</sub> < 5%CuCeO<sub>x</sub> < 20%CuCeO<sub>x</sub> < 30%CuCeO<sub>x</sub> < 60%CuCeO<sub>x</sub> < CuO < CeO<sub>2</sub>.

Table 5 reports the hydrogen uptakes measured during the H<sub>2</sub>-TPR analysis. As a whole, the higher the Cu content, the higher the H<sub>2</sub> consumption. Moreover, the H<sub>2</sub>-to-Cu consumption ratio was estimated and reported in Table 5. This value corresponds to the ratio between the H<sub>2</sub> consumed during the TPR analysis and the stoichiometric amount of H<sub>2</sub> required to reduce the Cu<sup>2+</sup> species contained in the samples. Notably, the CuCeO<sub>x</sub> catalysts present higher H<sub>2</sub>-to-Cu consumption with respect to pure CuO, indicating that the Cu<sup>2+</sup> reduction is accompanied by the reduction of Ce<sup>4+</sup> to Ce<sup>3+</sup> [17].

**Table 5.** Hydrogen consumption (mmol g<sup>−1</sup>) evaluated by H<sub>2</sub>-TPR.

	H <sub>2</sub> -Uptake Total	H <sub>2</sub> /Cu	H <sub>2</sub> -Uptake <200 °C	H <sub>2</sub> -Uptake 200–400 °C	H <sub>2</sub> -Uptake 400–500 °C	H <sub>2</sub> -Uptake >500 °C
CeO <sub>2</sub>	1.41	-	0.01	0.11	0.16	1.13
5%CuCeO <sub>x</sub>	1.33	3.46	0.16	0.52	0.05	0.60
10%CuCeO <sub>x</sub>	1.91	1.50	0.15	1.21	0.06	0.49
20%CuCeO <sub>x</sub>	3.59	1.34	0.09	2.52	0.30	0.68
30%CuCeO <sub>x</sub>	5.35	1.27	0.05	4.07	0.43	0.79
60%CuCeO <sub>x</sub>	8.83	1.11	0.02	5.86	1.99	0.96
CuO	12.57	1.00	0.00	4.37	5.92	2.28

### 3.3. Catalytic Activity

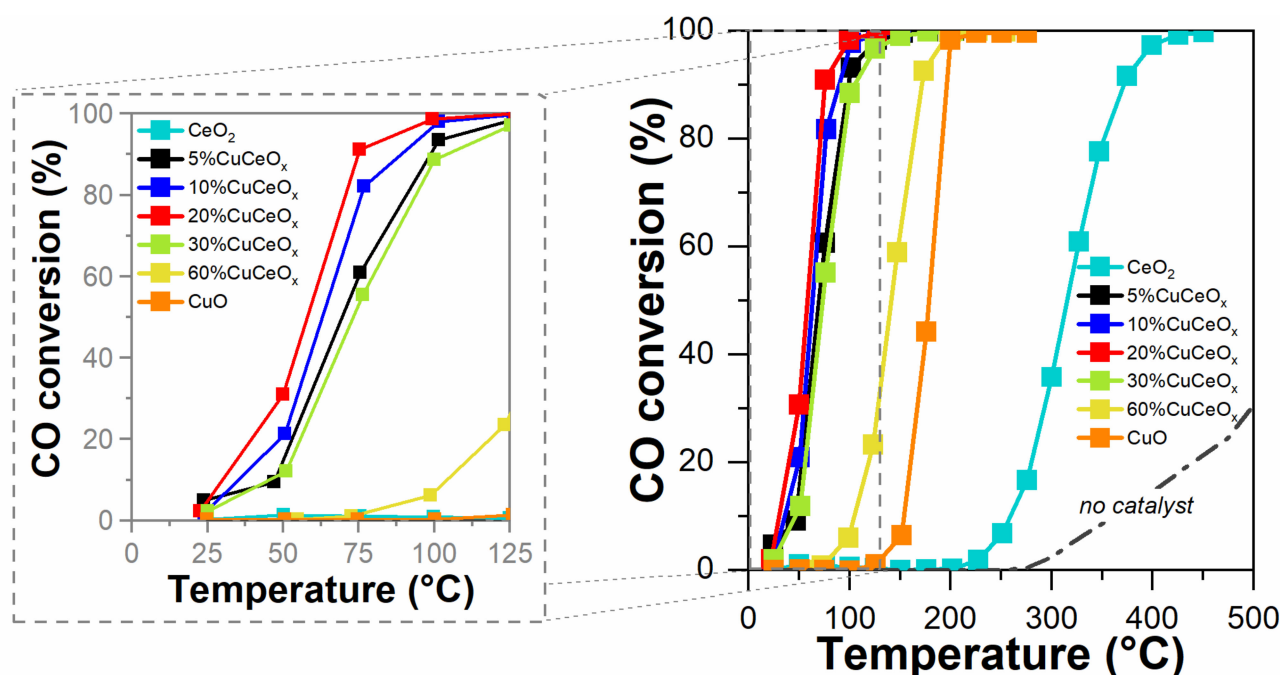

#### 3.3.1. CO Oxidation Reaction

The results of the CO oxidation tests are shown in Figure 7. The CO conversion (%) is reported as a function of the temperature and the catalytic tests were compared with the non-catalytic one (labeled as “no-catalyst”). The red graph displays a magnification in the range between 0 and 125 °C for a better comprehension. Moreover, Table 6 reports the temperatures at which the catalysts convert the 10, 50 or 90% of CO (T<sub>10%</sub>, T<sub>50%</sub> and T<sub>90%</sub>, respectively) and the CO oxidation rates (μmol h<sup>−1</sup> g<sup>−1</sup>) evaluated at 50 °C.

As a whole, all the samples exhibit good catalytic performances comparing to the thermal CO oxidation (no catalyst). Interestingly, the most performing sample is 20%CuCeO<sub>x</sub>: in fact, the CO complete oxidation occurs at 125 °C in the presence of this catalyst. On the other hand, pure CeO<sub>2</sub> presents the worst performance. In detail, as can be seen in Figure 7, the catalytic activity follows this increasing reaction order: CeO<sub>2</sub> < CuO < 60%CuCeO<sub>x</sub> < 30%CuCeO<sub>x</sub> < 5%CuCeO<sub>x</sub> < 10%CuCeO<sub>x</sub> < 20%CuCeO<sub>x</sub>.

In order to explain the good catalytic performance of the 20%CuCeO<sub>x</sub> sample, Figure 8 reports the values of O<sub>α</sub> abundancy (at.%), Ce<sup>3+</sup> abundancy (at.%), D/F<sub>2g</sub> ratio and the CO oxidation rate (μmol h<sup>−1</sup> g<sup>−1</sup>) as a function of the Cu content (wt.%). As a whole, a good correspondence was found among the trends of all these parameters. In particular, the Pearson correlation coefficients (reported in Table S2) point out that the catalytic activity for CO oxidation is primarily linked to the presence of reactive O<sub>α</sub> species, followed by the quantity of structural defects and lastly by the abundance of Ce<sup>3+</sup> ions.

**Figure 7.** CO conversion as a function of the temperature in the range 0–500 °C (black graph) and a magnification in the range 0–125 °C (grey graph).

**Table 6.** Catalytic performances of the prepared samples in the catalytic oxidation of CO.

Catalyst	CO Oxidation Rate <sup>a</sup> ( $\mu\text{mol h}^{-1} \text{g}^{-1}$ )	T <sub>parameter</sub> (°C)		
		T <sub>10%</sub>	T <sub>50%</sub>	T <sub>90%</sub>
CeO <sub>2</sub>	$2.6 \times 10^{-2}$	258	314	372
5%CuCeO <sub>x</sub>	171	46	69	98
10%CuCeO <sub>x</sub>	257	35	62	90
20%CuCeO <sub>x</sub>	375	30	58	75
30%CuCeO <sub>x</sub>	138	46	73	105
60%CuCeO <sub>x</sub>	$2.7 \times 10^{-4}$	104	139	171
CuO	$3.7 \times 10^{-4}$	151	179	197

<sup>a</sup> Calculated at 50 °C.

Actually, defect sites and Ce<sup>3+</sup> species are directly involved in the Mars–van Krevelen-type reaction mechanism. This mechanism implies the oxidation of CO by means of structural oxygen, leaving a defective site (i.e., an oxygen vacancy) that is then replenished (oxidized) by gas phase O<sub>2</sub> [65,85]. Moreover, the O<sub>α</sub> species, consisting of chemisorbed oxygen on the catalyst surface, are also highly reactive during the oxidation processes. Hence, the higher the amount of defects, Ce<sup>3+</sup> and O<sub>α</sub> species, the higher the oxidative performance of the catalyst.

Consequently, the 20%CuCeO<sub>x</sub> mixed oxide, which exhibits the largest quantity of defect sites, O<sub>α</sub> and Ce<sup>3+</sup> species, has the highest CO oxidation rate. The 5%CuCeO<sub>x</sub> and 10%CuCeO<sub>x</sub> samples exhibit similar reducibility properties to 20%CuCeO<sub>x</sub> (see Figure 6), but their lower abundance of O<sub>α</sub>, Ce<sup>3+</sup> and structural defects is likely responsible for their slightly lower catalytic activity.

**Figure 8.** Trends of various parameters of the different CuCeO<sub>x</sub> catalysts reported as a function of the Cu wt.% content.

The CO oxidation performances of the 20%CuCeO<sub>x</sub> sample were compared with those of the most performing catalysts studied in references [17,86–92]. The latter research works deal with copper-cerium based catalysts synthesized by means of different co-precipitation techniques, such as Solution Combustion Synthesis (SCS) [17,86], Sol-gel [87,88], hydrothermal [89,90] and wet impregnation method [91,92]. The comparison, in terms of T<sub>50%</sub> for CO oxidation, is shown in Figure 9.

**Figure 9.** Comparison of the T<sub>50%</sub> accomplished during the CO oxidation among the most performing copper-cerium based catalysts synthesized by different techniques reported in the literature and the 20%CuCeO<sub>x</sub> sample studied in this work.

The 20%CuCeO<sub>x</sub> sample exhibits the lowest  $T_{50\%}$  (58 °C) comparing with the other Cu–Ce mixed catalysts. Then, a last comparison was performed with Pt/CeO<sub>2</sub> catalysts studied in references [93–95] and it is possible to conclude the CuCeO<sub>x</sub> samples show good low-temperature CO oxidation activity compared with ceria-supported noble-metal. Thus, the MIVR method represents a promising synthesis procedure, since it enables to obtain CuCeO<sub>x</sub> nanocatalysts with very interesting physico-chemical and catalytic properties.

In order to investigate the effect of the co-presence of CeO<sub>x</sub> and Cu<sub>x</sub>O phases, the CO oxidation rates listed in Table 6 are plotted in Figure 10 as a function of the Cu weight content. A growing trend could be observed for Cu doping ranging from 5 to 20 wt.%, while a decreasing one was noticed upon further Cu addition. As previously described, the sample containing the 20 wt.% of Cu exhibits the highest reaction rate (375  $\mu\text{mol h}^{-1} \text{g}^{-1}$ ).

**Figure 10.** Specific reaction rates of CO oxidation accomplished over the powder catalysts at 50 °C as a function of the Cu wt.%.

Moreover, Figure 10 shows a black dashed line representing the theoretical reaction rate of a mixture of completely non-interacting CeO<sub>2</sub> and CuO phases. This hypothetical rate is defined by the following linear function (Equation (1)):

$$r_i = r_{\text{CeO}_2} x_{\text{CeO}_2} + r_{\text{CuO}} x_{\text{CuO}} \quad (1)$$

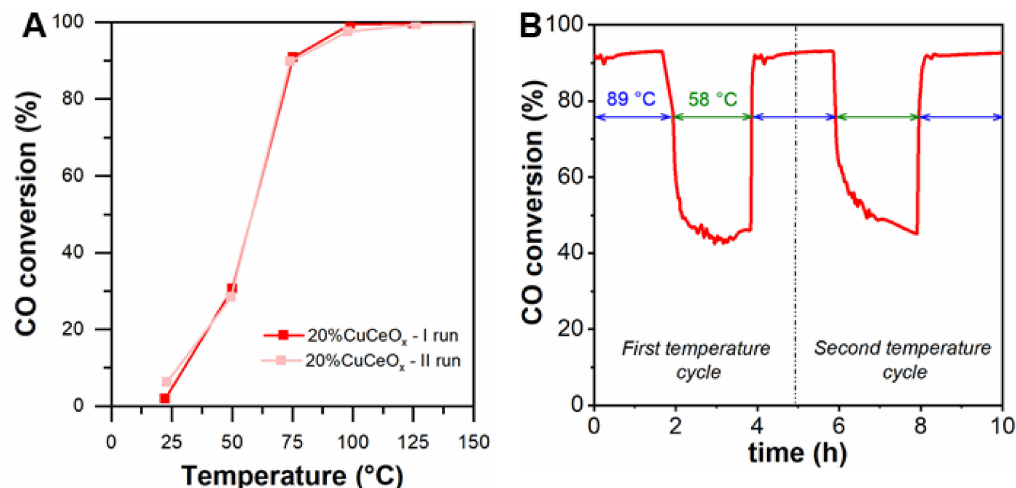

where  $r_i$  represents the theoretical reaction rate,  $r_{\text{CeO}_2}$  and  $r_{\text{CuO}}$  the reaction rates of cerium and copper oxide, respectively, while  $x_{\text{CeO}_2}$  and  $x_{\text{CuO}}$  are the mass fractions of cerium and copper oxide. In Figure 10, the red dashed line represents the actual trend of the reaction rates. Interestingly, for all the mixed samples, the real CO oxidation rates are above the theoretical ones (the black dashed line). Thus, a synergistic effect between the two active phases is occurring [96].

Similarly, the  $T_{10\%}$  was reported in Figure S4 as a function of the Cu wt.% content. The theoretical  $T_i$  value is represented by the following equation (Equation (2)):

$$T_i = T_{\text{CeO}_2} x_{\text{CeO}_2} + T_{\text{CuO}} x_{\text{CuO}} \quad (2)$$

where  $T_i$  represents the theoretical  $T_{10\%}$ ,  $T_{\text{CeO}_2}$  and  $T_{\text{CuO}}$  the  $T_{10\%}$  of cerium and copper oxide, respectively, while  $x_{\text{CeO}_2}$  and  $x_{\text{CuO}}$  are the mass fractions of cerium and copper oxide. It appears that the two oxide phases exhibit a positive collaboration in agreement with the results reported in terms of reaction rates (Figure 10).

In order to assess the stability of the most performing catalyst (20%CuCeO<sub>x</sub>), two consecutive CO oxidation tests were carried out, and the results are reported in Figure 11A. The 20%CuCeO<sub>x</sub> sample exhibits good catalytic stability since reproducible results were achieved after the two consecutive runs.

**Figure 11.** (A) Thermal stability study of the 20%CuCeO<sub>x</sub> for two consecutive CO oxidation tests and (B) CO conversion (%) over the time during the long-term stability test for the 20%CuCeO<sub>x</sub> sample.

Moreover, another stability test was performed on this sample and reported in Figure 11B. During this test, the T<sub>50%</sub> and T<sub>95%</sub> were chosen and alternated for two consecutive cycles as follows:

- First cycle: the starting temperature was fixed to 89 °C, at which the catalyst exhibits a CO conversion of about 95% and this temperature was kept constant for 2 h. Then, the catalytic system was cooled down until 58 °C (T<sub>50%</sub>) and it was kept constant for other 2 h. After that, the temperature was increased until 89 °C. Hence, the first cycle is characterized by a Time-on-Stream (TOS) of about 5 h.
- Second cycle: the same as the first one.

As a whole, the 20%CuCeO<sub>x</sub> catalyst is able to reach, during the second cycle, the same conversion achieved during the first one. It is therefore possible to that the 20%CuCeO<sub>x</sub> catalyst exhibits not only a notable activity but also good stability properties since, after two cycles, its performance is fully preserved.

### 3.3.2. Ethene Oxidation Reaction

The catalytic performances of the synthesized materials measured during the catalytic oxidation of ethene are displayed in Figure 12. The presence of the prepared catalysts allowed the conversion of ethene at lower temperatures, compared to those of the blank test (i.e., the test where no catalyst was present).

Consistently, the catalytic improvement is confirmed by the rates of the ethene oxidation reaction calculated at 175 °C, as included in Table 7. As a whole, considering the catalytic performances reported in Figure 12, a catalytic activity trend for the CuCeO<sub>x</sub> samples can be outlined, as follows: 20%CuCeO<sub>x</sub> > 10%CuCeO<sub>x</sub> > 5%CuCeO<sub>x</sub> > 30%CuCeO<sub>x</sub> > 60%CuCeO<sub>x</sub>.

**Figure 12.** Catalytic conversion (%) of ethene over the synthesized catalysts as a function of the temperature.

**Table 7.** Catalytic performances of the prepared samples in the catalytic oxidation of  $C_2H_4$ .

Catalyst	Ethene Oxidation Rate <sup>a</sup> ( $\mu\text{mol h}^{-1} \text{g}^{-1}$ )	T <sub>parameter</sub> (°C)		
		T <sub>10%</sub>	T <sub>50%</sub>	T <sub>90%</sub>
CeO <sub>2</sub>	15	275	345	396
5%CuCeO <sub>x</sub>	25	194	238	273
10%CuCeO <sub>x</sub>	56	177	223	259
20%CuCeO <sub>x</sub>	62	175	221	252
30%CuCeO <sub>x</sub>	26	197	242	277
60%CuCeO <sub>x</sub>	21	217	290	357
CuO	3	237	287	328

<sup>a</sup> Calculated at 175 °C.

The catalyst containing the lowest loading of Cu (i.e., 5%CuCeO<sub>x</sub>) evidenced an overall improved catalytic performance compared to the parent CeO<sub>2</sub>, thus highlighting the beneficial effect of incorporating Cu species in the ceria structure (as observed in XRD and Raman analyses). Interestingly, an enhancement of the reaction rate was observed for the prepared set of mixed oxide catalysts (see Figure 13).

As observed in Figure 13, the ethene oxidation rates were in all cases above the theoretical (linear) trend drawn between CeO<sub>2</sub> and CuO (see black dashed line). The mentioned baseline represents an ideal estimation of the reaction rate as if it depended only on the relative amounts of non-interacting CeO<sub>2</sub> and CuO in a mixed sample, as reported in Equation (1) of Section 3.3.1.

**Figure 13.** Ethene catalytic oxidation reaction rate behavior as a function of the Cu loading in the prepared catalysts.

Consistently, the increased reaction rates verified for the whole set of mixed oxides (compared to the ideal behavior) evidence that beneficial interactions are taking place between the active components present in the catalysts. Moreover, this result is supported by the trend observed in Figure S5 for the temperatures needed for converting 10% of the ethene present in the gaseous stream (i.e., the  $T_{10\%}$  parameter). In fact, this improvement coincides with the contemporary presence of small CuO crystallites along with CeO<sub>2</sub> in the catalysts (as demonstrated by means of XRD, *vide supra*). In this sense, the overall catalytic performance varies (in terms of ethene reaction rate and  $T_{10\%}$ ) as a function of the size of CuO crystallites (as reported in Figure S6) and evidenced the following: the smaller the size of CuO crystallites in contact with CeO<sub>2</sub>, the better the catalytic performance in ethene oxidation.

Moreover, there is a positive correlation between the catalytic activity and some physico-chemical properties, namely, the amount of defect sites (*vide* Raman spectroscopy) and the  $O_{\alpha}/O_{\beta}$  ratio (*vide* XPS). The catalytic behavior (in terms of  $T_{X\%}$ ), as a function of the aforementioned properties is reported in Figure S7. Accordingly, the trends evidence that the higher the amount of  $O_{\alpha}$  species and lattice defects, the better the catalytic performance. As well, XPS revealed that the most active catalysts (i.e., the 20%CuCeO<sub>x</sub> followed by the 10%CuCeO<sub>x</sub>) contained elevated amounts of Ce<sup>3+</sup> species (see Table 3).

This complex scenario evidences that synergistic interactions are most likely taking place between CuO and CeO<sub>2</sub> and leading to a marked improvement of the catalytic oxidation of ethene (Figure 13). As reported in the literature, smaller particles may contain a higher number of crystal edges and corners, and thus an increased number of structural defects and reactive sites that may improve the catalytic performance [97]. On the other hand, electrophilic  $O_{\alpha}$  species are highly active in the oxidation of hydrocarbons [16,98,99]. Consistently, the elevated amounts of active  $O_{\alpha}$  species (that can participate in spillover phenomena between CeO<sub>2</sub>–CuO phases) could contribute to the catalytic activity of the ceria-based catalysts prepared in this work. Moreover, the results highlight the positive effect of defective sites for the ethene catalytic oxidation reaction.

Similarly to CO oxidation, the catalytic oxidation of VOCs over ceria-based materials could also be modeled as a redox process occurring at the catalytic surface known as

Mars–van Krevelen reaction mechanism [100,101]. However, the literature highlights the complexity of VOCs oxidation mechanism over oxide catalysts, as a function of the nature of the reactant molecules and of the catalytic materials [100–103].

#### 4. Conclusions

In this study, CuCeO<sub>x</sub> catalysts prepared by the Multi-Inlet Vortex Reactor (MIVR), were carefully characterized and tested towards the CO and ethene oxidation reactions. The results pointed out that the MIVR procedure can be effective to synthesize mixed oxides with promising physico-chemical properties and catalytic oxidation activity.

The CuCeO<sub>x</sub> mixed catalysts present much better CO oxidation performances with respect to pure CeO<sub>2</sub> due to the co-presence of CeO<sub>2</sub> and CuO phases that cooperate during the catalytic cycle. Interestingly, this set of samples is featured by outstanding catalytic activities comparing with the literature results of other copper-cerium based catalyst prepared by different co-precipitation methods and with Pt/CeO<sub>2</sub>-type catalysts. The most promising catalyst is the 20%CuCeO<sub>x</sub> sample, thanks to its optimized physico-chemical properties: good textural-structural properties (SSA, V<sub>p</sub> and D<sub>c</sub>), high amount of structural defects (such as oxygen vacancies and Frenkel sites), and great availability of Ce<sup>3+</sup> and O<sub>α</sub> species. This catalyst also exhibited a considerable thermal stability.

The catalytic activity for the oxidation of ethene was observed to vary according to the amount of copper present in the catalyst. Overall, the best catalytic performance for ethene oxidation was observed for the 20%CuCeO<sub>x</sub> catalyst. The catalytic activity was ascribed to the contemporary presence of CeO<sub>2</sub> and CuO phases and to their possible synergistic interactions. Moreover, the catalytic performance in ethene abatement increased when the size of the CuO particles decreased, i.e., the smaller the size of CuO particles, the higher the catalytic activity. Finally, it was observed that the occurrence of elevated relative amounts of (i) chemisorbed O<sub>α</sub> species and (ii) defect sites positively contribute to the catalytic performances in ethene oxidation.
