Linear Lipschitz and C^1 extension operators through random projection

Elia Bruè*

Simone Di Marino[†]Federico Stra[‡]

October 16, 2018

Abstract

We construct a regular random projection of a metric space onto a closed doubling subset and use it to linearly extend Lipschitz and C^1 functions. This way we prove more directly a result by Lee and Naor [LN05] and we generalize the C^1 extension theorem by Whitney [Whi34] to Banach spaces.

1 Introduction

The aim is to provide extension theorems $\text{Lip}(X; Z) \rightarrow \text{Lip}(Y; Z)$ where $X \subset Y$ is a closed subset of a complete metric space (Y, d) and Z is a Banach space, under hypotheses just on the space X alone and not on the ambient space Y .

In [LN05] the authors provide the following extension theorem for Lipschitz functions in a metric setting.

*Scuola Normale Superiore, Pisa, elia.brue@sns.it

[†]Indam, Unità SNS, Pisa, simone.dimarino@altamatematica.it

[‡]Scuola Normale Superiore, Pisa, federico.stra@sns.it

Theorem (Lee and Naor [LN05]). *Let $X \subset (Y, d)$ be a doubling metric space with doubling constant λ_X . Then there is an extension $T : \text{Lip}(X; Z) \rightarrow \text{Lip}(Y; Z)$ such that*

$$\text{Lip}(Tf) \leq C \log(\lambda_X) \text{Lip}(f) \quad \forall f \in \text{Lip}(X; Z),$$

where C is a universal constant.

Our goal is to obtain more directly the previous result, through a simpler proof based on ideas appearing in [JLS86]. See also [LN04; Oht09] for related discussions. With this method, we can provide also a C^1 extension result in the spirit of Whitney [Whi34].

In Section 4.1 we also have a simple and very short proof of the Lipschitz extension result which is self-contained and based solely on the existence of a doubling measure on a doubling space.

The main theorems are Theorem 4.1 for the Lipschitz extension and Theorem 4.3 for the C^1 extension respectively. The structure is as follows: in Section 2 we construct partitions of unity, both in the Lipschitz and C^1 version; in Section 3 we use these partitions to build Lipschitz and C^1 random projections of a space onto a subspace and finally in Section 4 we prove the extension theorems using the previously developed tools.

1.1 Notation and preliminaries

Let (X, d) be a complete metric space. We will denote with $B(x, r)$ the open ball of radius r , centered at x and, for $A \subseteq X$, we define $d(x, A) = \inf\{d(x, x') : x' \in A\}$.

We will denote by $\text{Lip}(X; Z)$ the set of Lipschitz functions with values in Z ; if the second space is dropped it means that $Z = \mathbb{R}$. Moreover, given $f \in \text{Lip}(X; Z)$, we denote by $\text{Lip}(f)$ the least Lipschitz constant for the function f . We make use of the notion of slope of a function $f : X \rightarrow \mathbb{R}$ defined as

$$|\nabla f|(x) = \limsup_{y \rightarrow x} \frac{|f(y) - f(x)|}{d(y, x)}.$$

We will be dealing with measures supported in metric spaces: we denote by $\mathcal{P}(X)$ the set of Borel probability measures on X , with $\mathcal{M}_+(X)$ the set of finite nonnegative Borel measures on X and with $\mathcal{M}(X; Z)$ the set of vector valued measures with finite total variation. As before, if the second spaces is omitted then $Z = \mathbb{R}$ and so it will reduce to the space of signed measures.

Of crucial importance in the sequel will be the W_1 Wasserstein distance. We recall here just the dual representation instead of the direct one because it will be the more relevant for the further development. We will define it as usual on $\mathcal{P}_1(X)$, where

$$\mathcal{P}_1(X) = \left\{ \mu \in \mathcal{P}(X) : \int_X d(x, x_0) d\mu(x), \text{ for some } x_0 \in X \right\}.$$

Definition 1.1 (Wasserstein distance). Let $\mu_1, \mu_2 \in \mathcal{P}_1(X)$. Then we define

$$W_1(\mu, \nu) = \sup \left\{ \int_X f d\mu - \int_X f d\nu : f \in \text{Lip}(X), \text{Lip}(f) \leq 1 \right\}.$$

Remark 1.2. Notice that there is no harm in defining W_1 only on $\mathcal{P}_1(X)$, since in the sequel we will deal only with probabilities with bounded supports, which clearly belong to $\mathcal{P}_1(X)$. A useful inequality that follows directly from the definition is

$$\left| \int_X f \, d\mu_1 - \int_X f \, d\mu_2 \right| \leq \text{Lip}(f) W_1(\mu_1, \mu_2). \quad (1.1)$$

Throughout the paper we use the notation \lesssim to omit a universal constant not depending on X , Y , the doubling constant λ or anything of this sort. We will use two notion of dimensionality of a metric space: the *doubling constant* and the *metric capacity*.

Definition 1.3 (Doubling metric space). (X, d) is a doubling metric space if there exists $\lambda \in \mathbb{N}$ such that every ball of radius $2r$ can be covered with at most λ balls of radius r . The least such constant is λ_X , the doubling constant of X ¹.

Definition 1.4 (Metric capacity). Given a metric space (X, d) we define the *metric capacity*² $\kappa_X : (0, 1] \rightarrow \mathbb{N} \cup \{\infty\}$ as

$$\kappa_X(\varepsilon) = \sup \left\{ k : \exists x_0, \dots, x_k \in X, \exists r > 0 \text{ s.t. } \bigsqcup_{i=1}^k B(x_i, \varepsilon r) \subset B(x_0, r) \right\},$$

where the notation $\bigsqcup_{i=1}^k B(x_i, \varepsilon r)$ indicate a *disjoint* union of balls.

It can be verified that if $\kappa_X(\varepsilon) < \infty$ for some $\varepsilon < 1/3$, then $\kappa_X(t)$ is finite for every $t \in (0, 1]$. Even if it is true that X has a finite doubling constant iff X has a finite metric capacity, it is more natural to use the latter in some of the constructions. However since we want the final result to depend only on the doubling constant of X , we will make use of the following proposition comparing λ and κ .

Proposition 1.5 (Comparing κ and λ). *Let X be a metric space. Then we have that*

- (i) $\lambda \leq \kappa_X(1/5)$;
- (ii) $\kappa_X(\varepsilon) \leq \lambda^k$ whenever $\frac{1}{2^k} < \varepsilon \leq \frac{1}{2^{k-1}}$.

Proof. Considering a maximal family $\mathcal{F} = \{B(x_i, \varepsilon r)\}_{i \in I}$ of disjoint balls contained in $B(x_0, r)$ we have $|\mathcal{F}| \leq \kappa(\varepsilon)$ and moreover $B(x_0, (1 - \varepsilon)r) \subseteq \cup_i B(x_i, 2\varepsilon r)$. Choosing $\varepsilon = 1/5$ and thanks to the arbitrariness of r and x_0 we get that $\lambda \leq \kappa_X(1/5)$.

In order to prove the second inequality we first observe that for we can cover $B(x_0, 2^k r)$ with less than λ^k balls of radius r : let us consider $\mathcal{F}' = \{B(y_i, r)\}$ such a family. Let $\frac{1}{2^k} < \varepsilon \leq \frac{1}{2^{k-1}}$ and $\mathcal{F} = \{B(x_i, \varepsilon 2^k r)\}$ be a disjoint family of balls contained in $B(x_0, 2^k r)$. It is now easy to see that $B(y_i, r)$ can contain at most one x_i ; then we have $|\mathcal{F}| \leq |\mathcal{F}'| \leq \lambda^k$ and so $\kappa_X(\varepsilon) \leq \lambda^k$. □

¹In the sequel we will drop the dependence on X when there is no room for confusion

²For short, just *capacity* in the sequel.

2 Whitney-type partitions

The way to the extension results follows the same path traced by Whitney for his theorem [add reference], with the addition of some ideas that we have learnt from [JLS86]. The first step is to construct suitable partitions of unity so that manually built local extensions can be patched together at the global level. Since our goal is to prove Lipschitz and C^1 extendability, we are going to need two different kind of partitions, one for each purpose. The underlying ideas are the same in both cases; in particular, the attentive reader will notice that in the C^1 construction we try to replicate the proof of the Lipschitz version, with appropriate modifications.

Proposition 2.1 (Relative Lipschitz partition of unity). *Let (Y, d) be a metric space and $X \subset Y$ a closed subset with finite doubling constant λ . Then there exists a countable family $\{V_i, \varphi_i, x_i\}_i$ such that:*

- (i) $\{V_i\}_i$ is a locally finite covering of $Y \setminus X$ with covering constant $3\lambda^4$;
- (ii) $\{\varphi_i\}_i$ is a partition of unity on $Y \setminus X$ such that $\{\varphi_i > 0\} \subset V_i$ and

$$\sum_i |\nabla \varphi_i|(y) \lesssim \frac{\log \lambda}{d(y, X)};$$

- (iii) the points x_i belong to X and $d(y, x_i) \lesssim d(y, X)$ if $y \in V_i$.

Proof. This follows directly from Lemma 2.5 below, re-indexing the family $\{V_i^n, \varphi_i^n, x_i^n\}_{i,n}$. \square

The idea is that thanks to (iii) we have that x_i is an approximate projection of any $y \in V_i$ on X and in fact this partition of unity will help us define a *random projection*. The estimate (ii) will be instead crucial to prove Lipschitz estimates. The next proposition will be used to prove an extension of Whitney theorem for Banach spaces, requiring the partition of unity to be C^1 . Unfortunately the dependence of λ in the estimates of the slopes is much worse in this case: it will be interesting to have a class of Banach spaces where we can recover the same logarithmic behavior as in the Lipschitz case.

Proposition 2.2 (Relative C^1 partition of unity). *Let Y be a Banach space whose norm belongs to $C^1(Y \setminus \{0\})$ and let $X \subset Y$ be a closed subset with doubling constant λ . Then there exists a family $\{V_i, \varphi_i, x_i\}_i$ such that:*

- (i) $\{V_i\}_i$ is a locally finite covering of $Y \setminus X$ with covering constant $5\lambda^4$;
- (ii) $\{\varphi_i\}_i$ is a partition of unity on $Y \setminus X$ such that $\{\varphi_i > 0\} \subset V_i$ and

$$\sum_i |\nabla \varphi_i|(y) \lesssim \frac{\lambda^4 \log \lambda}{d(y, X)};$$

moreover $\varphi_i \in C^1(Y)$ for every $i \in \mathbb{N}$.

- (iii) the points x_i belong to X and $d(y, x_i) \lesssim d(y, X)$ if $y \in V_i$.

Proof. This follows directly from Lemma 2.6, taking the family $\{A_i^n, \varphi_i^n, x_i^n\}_{i,n}$. \square

We now state and prove a simple technical lemma, crucial in the construction of the Whitney-type covering in Lemma 2.4.

Lemma 2.3. *Let (X, d) be a metric space. Then for every $r > 0$ there exists a family of disjoint balls $\{(B_i = B(x_i, r))\}_{i \in I}$ such that $\{2B_i = B(x_i, 2r)\}_{i \in I}$ is a covering of X .*

Proof. Let $\mathcal{F} = \{(B_i)_{i \in I} : B_i \cap B_j = \emptyset\}$ be the collection of all disjoint families of open balls of radius r . A simple application of Zorn's lemma shows that there exist a maximal family $(B_i)_{i \in I}$. Suppose by contradiction that $x \notin 2B_i$ for any $i \in I$. Then $B(x, r)$ is disjoint from every B_i , contradicting the maximality. \square

Lemma 2.4 (Whitney-type covering). *Let (Y, d) be a complete metric space and $X \subset Y$ a closed subset with finite capacity. For every $n \in \mathbb{Z}$ let $\{B_i^n = B(x_i^n, 2^n)\}_{i \in I_n}$ be a family given by Lemma 2.3. Let*

$$\tilde{V}_i^n = \{y \in Y \setminus X : 2^n \leq d(y, X) < 2^{n+1} \text{ and } d(y, x_i^n) = \min_{j \in I_n} d(y, x_j^n)\}.$$

Then the family of enlarged sets $\mathcal{F} = \{V_i^n = (\tilde{V}_i^n)_{2^{n-1}} : n \in \mathbb{Z}, i \in I_n\}$ has the following properties:

- (i) \mathcal{F} is a locally finite covering of $Y \setminus X$ with constant $3\kappa_X(1/10)$;
- (ii) for every $y \in Y \setminus X$ we have $d(y, X)/4 \leq \max_{V \in \mathcal{F}} \{d(y, V^c)\} \leq d(y, X)$.

Proof. First of all, it is obvious that \mathcal{F} is a covering: in fact also $\{\tilde{V}_i^n\}_{i,n}$ is a covering. Let us prove that for $y \in V_i^n$ we have $d(y, x_i^n) \leq 9 \cdot 2^{n-1}$. By definition, for every $\varepsilon > 0$ there exists $\tilde{y} \in \tilde{V}_i^n$ and $x \in X$ such that

$$d(y, \tilde{y}) < d(y, \tilde{V}_i^n) + \varepsilon \leq 2^{n-1} + \varepsilon \quad \text{and} \quad d(\tilde{y}, x) < d(\tilde{y}, X) + \varepsilon \leq 2^{n+1} + \varepsilon.$$

Then, by the covering property of $\{2B_i^n\}_{i \in I_n}$ we know that there exists j such that $x \in 2B_j^n$ and so $d(x, x_j^n) \leq 2^{n+1}$. In particular, by definition of \tilde{V}_i^n we obtain

$$\begin{aligned} d(y, x_i^n) &\leq d(\tilde{y}, x_i^n) + d(\tilde{y}, y) \leq d(\tilde{y}, x_j^n) + d(\tilde{y}, y) \\ &\leq d(\tilde{y}, x) + d(x, x_j^n) + d(\tilde{y}, y) \leq 9 \cdot 2^{n-1} + 2\varepsilon. \end{aligned}$$

In order to get the local finiteness in (i) we use the fact that if $y \in V_i^n \cap V_j^n$ then we have $d(y, x_i^n) \leq 9 \cdot 2^{n-1}$ and $d(y, x_j^n) \leq 9 \cdot 2^{n-1}$. In particular we have $x_j^n \in B(x_i^n, 9 \cdot 2^n)$ and so $B(x_j^n, 2^n) \subseteq B(x_i^n, 10 \cdot 2^n)$. In particular we get that $\#\{j : y \in V_j^n\} \leq \kappa_X(1/10)$. Now, knowing that $y \in V_i^n$ implies $2^{n-1} < d(y, X) < 2^{n+2}$ we have at most three possible choices for n and at most $\kappa_X(1/10)$ sets for every n , so the conclusion.

For (ii) the inequality $\max_{V \in \mathcal{F}} \{d(y, V^c)\} \leq d(y, X)$ is trivial since $X \subset V^c$ for all V . For the other inequality we know that $y \in \tilde{V}_i^n$ for some i, n and in particular we have $d(y, (V_i^n)^c) \geq 2^{n-1}$ by the definition of V_i^n . But then we have

$$\frac{d(y, X)}{4} < 2^{n-1} \leq d(y, (V_i^n)^c) \leq \max_{V \in \mathcal{F}} \{d(y, V^c)\}. \quad \square$$

In the final part of this section we build the two families of partitions of unity: the first one is made by Lipschitz functions (Lemma 2.5) and the second, more regular, it is composed by $C^1(Y)$ functions (Lemma 2.6).

Lemma 2.5 (Lipschitz partition of unity). *Let $\{V_i^n\}_{i,n}$ be the sets given by Lemma 2.4. For $m > 0$ define the functions*

$$\tilde{\varphi}_i^n(y) = \mathbf{d}^m(y, (V_i^n)^c) \quad \text{and} \quad \varphi_i^n(y) = \frac{\tilde{\varphi}_i^n(y)}{\sum_{k,j} \tilde{\varphi}_j^k(y)}.$$

Then the family $\{\varphi_i^n\}_i^n$ is a partition of unity with the property that

$$\sum_{n,i} |\nabla \varphi_i^n|(y) \lesssim \frac{\log \lambda}{\mathbf{d}(y, X)}.$$

Proof. Thanks to the sublinearity of the slope, the chain rule, and the fact that $|\nabla \mathbf{d}(y, A)| \leq 1$ for every A , we obtain

$$|\nabla \varphi_i^n|(y) \leq m \frac{\mathbf{d}^{m-1}(y, (V_i^n)^c)}{\sum_{k,j} \mathbf{d}^m(y, (V_j^k)^c)} + m \frac{\mathbf{d}^m(y, (V_i^n)^c) \cdot \sum_{k,j} \mathbf{d}^{m-1}(y, (V_j^k)^c)}{\left(\sum_{k,j} \mathbf{d}^m(y, (V_j^k)^c)\right)^2}.$$

In order to have a clearer exposition, we fix $\{\mathbf{d}_l\}_{l \in \{1, \dots, N\}} = \{\mathbf{d}^{m-1}(y, (V_j^k)^c)\}_{j,k}$ where we included all couples j, k such that $y \in V_j^k$; in particular we have $N \leq 2\kappa_X(1/10)$. Then summing up on the indices i, n and simplifying we get

$$\sum_{i,n} |\nabla \varphi_i^n|(y) \leq m \frac{\sum_l \mathbf{d}_l^{m-1}}{\sum_l \mathbf{d}_l^m} + m \frac{\sum_l \mathbf{d}_l^m \cdot \sum_l \mathbf{d}_l^{m-1}}{(\sum_l \mathbf{d}_l^m)^2} = 2m \frac{\sum_l \mathbf{d}_l^{m-1}}{\sum_l \mathbf{d}_l^m}.$$

Now we use the inequality between the means $\left(\frac{\sum_l \mathbf{d}_l^{m-1}}{N}\right)^{1/(m-1)} \leq \left(\frac{\sum_l \mathbf{d}_l^m}{N}\right)^{1/m}$, obtaining

$$\sum_{i,n} |\nabla \varphi_i^n|(y) \leq 2m \frac{N^{1/m}}{(\sum_l \mathbf{d}_l^m)^{1/m}}.$$

By Lemma 2.4 (ii), we have $\max_l \{\mathbf{d}_l\} \geq \mathbf{d}(y, X)/4$ and so, using Proposition 1.5 (ii) and then setting $m = \log_2 \lambda$ we find

$$|\nabla \varphi_i^n|(y) \leq 2m \frac{N^{1/m}}{\max_l \{\mathbf{d}_l\}} \leq \frac{8m(2\kappa(1/10))^{1/m}}{\mathbf{d}(y, X)} \leq 256 \frac{\log_2(\lambda)}{\mathbf{d}(y, X)}.$$

□

Lemma 2.6 (C^1 partition of unity). *Let X and Y be as in Proposition 2.2 and for every $n \in \mathbb{Z}$ let $\{B_i^n = B(x_i^n, 2^n)\}_{i \in I_n}$ be the family given by Lemma 2.3. Then there exists a partition of unity $\{\varphi_i^n\}_{i,n}$ of $Y \setminus X$ such that, denoting $A_i^n = \{\varphi_i^n > 0\}$, we have that*

(i) $\{A_i^n\}_{i,n}$ is a covering of $Y \setminus X$ with covering constant less than $C\lambda^6$;

(ii) if $y \in A_i^n$ then $\mathbf{d}(y, x_i^n) \lesssim \mathbf{d}(y, X)$;

(iii) $\sum_{i,n} |\nabla \varphi_i^n|(y) \lesssim \frac{\lambda^5 \log \lambda}{\mathbf{d}(y, X)}$.

Proof. The idea is to take

$$\varphi_i^n(y) = \frac{\tilde{\varphi}_i^n(y)}{\sum_{k,j} \tilde{\varphi}_j^k(y)},$$

where

$$\tilde{\varphi}_i^n(y) = \xi\left(8\ell - \frac{|x_i^n - y|}{2^n}\right) \cdot \xi\left(\frac{|x_i^n - y|}{2^n} - \ell\right) \cdot \prod_{x_j^n \sim x_i^n} \xi\left(\frac{|x_j^n - y|}{2^n} - \frac{|x_i^n - y|}{2^n} + \delta\right)$$

and

- $\delta \ll 1 \ll \ell$;
- $\xi : \mathbb{R} \rightarrow [0, 1]$ is a suitably chosen increasing C^1 function satisfying $\xi(t) = 0$ for $t \leq 0$ and $\xi(t) = 1$ for $t \geq \delta$,
- $\xi' \leq f(\xi)$ for a positive concave function $f : [0, \infty) \rightarrow [0, \infty)$ with $f(0) = 0$ to be specified later,
- the notation $x_j^n \sim x_i^n$ means that $|x_j^n - x_i^n| \leq 2^n(9\ell - \delta)$.

Fix $N = \kappa_X(1/(9\ell - \delta + 1))$. We will prove the lemma through the following steps.

- (a) $\tilde{\varphi}_i^n(y) > 0$ implies $(\ell - 2 - \delta)2^n \leq \mathbf{d}(y, X) \leq 8\ell \cdot 2^n$.
- (b) Let $I_n(y) = \{i \in I_n : \tilde{\varphi}_i^n(y) > 0\}$, then $|I_n(y)| \leq \kappa_X(1/(16\ell + 1))$. Moreover $|\{n : I_n(y) \neq \emptyset\}| \leq \lfloor \log_2(8\ell/(\ell - 2 - \delta)) \rfloor$.
- (c) $|\nabla \tilde{\varphi}_i^n|(y) \leq 2(N + 1)2^{-n} f(\tilde{\varphi}_i^n(y))$.
- (d) If $2\ell \leq \mathbf{d}(y, X)2^{-n} \leq 4\ell$ then there exists $i \in I_n$ such that

$$\tilde{\varphi}_i^n(y) \geq \xi(4\ell - 2)\xi(\ell)\xi(\delta)^N = 1,$$

so that in particular $\sum_{i,n} \tilde{\varphi}_i^n(y) \geq 1$ for every $y \in Y \setminus X$.

We start by proving (a). It is obvious that $\mathbf{d}(y, X) \leq |y - x_i^n| \leq 8\ell \cdot 2^n$. For the other inequality suppose by contradiction that there exists $x \in X$ such that $|y - x| < 2^n(\ell - 2 - \delta)$; then there exists j such that $|x - x_j^n| \leq 2^{n+1}$ and so, by triangle inequality we have $|x_j^n - x_i^n| \leq 2^n(9\ell - \delta)$ and in particular $x_j^n \sim x_i^n$. Then, using $\tilde{\varphi}_i^n(y) > 0$ we get

$$|y - x_j^n| \geq |y - x_i^n| - \delta 2^n \geq (\ell - \delta)2^n,$$

which is in contradiction with

$$|y - x_j^n| \leq |y - x| + |x - x_j^n| < (\ell - \delta)2^n.$$

In order to prove (b) we fix $i \in I_n(y)$ and observe that for all $j \in I_n(y)$ we have $|x_j^n - y| \leq 8\ell \cdot 2^n$, and in particular $|x_j^n - x_i^n| \leq 8\ell \cdot 2^{n+1}$, so that $B(x_j^n, 2^n) \subseteq$

$B(x_i^n, (16\ell + 1)2^n)$ and thus the conclusion follows using the definition of κ_X . For the second cardinality computation, assume that $y \in A_i^{n_1} \cap A_j^{n_2}$; then from (a) we deduce $|n_1 - n_2| \leq \log_2(8\ell/(\ell - 2 - \delta))$.

For (c) it is sufficient to use the chain rule, the fact that the distance to a fixed point is 1-Lipschitz and that $f(a)b \leq f(ab)$ for $a, b \leq 1$ because of the concavity.

The last point follows from taking $i \in I_n$ that minimizes $|y - x_i^n|$. In this way we have that all the factors in the last product are always bigger than $\xi(\delta)$. As for the first two factor, for sure we have $|y - x_i^n| \geq 2\ell \cdot 2^n$ and, calling \bar{y} a projection of y on X , there exists j such that $|x_j^n - \bar{y}| \leq 2^{n+1}$. By the minimality of i we get

$$|y - x_i^n| \leq |y - x_j^n| \leq |y - \bar{y}| + |x_j^n - \bar{y}| \leq 2^n(4\ell + 2).$$

These two inequalities let us conclude.

We now compute $|\nabla\varphi_i^n|$. Setting $K(y) = |\{(j, n) : \varphi_j^n(y) > 0\}|$, from (b) we deduce that

$$K(y) \leq \kappa_X(1/(16\ell + 1)) \lceil \log_2(8\ell/(\ell - 2 - \delta)) \rceil, \quad (2.1)$$

which implies (i). Now, using (c) we get

$$\begin{aligned} |\nabla\varphi_i^n|(y) &\leq \frac{2(N+1)}{2^n} \cdot \left(\frac{f(\tilde{\varphi}_i^n(y))}{\sum_{j,k} \tilde{\varphi}_j^k(y)} + \frac{\tilde{\varphi}_i^n(y)}{\sum_{j,k} \tilde{\varphi}_j^k(y)} \cdot \frac{\sum_{j,k} f(\tilde{\varphi}_j^k(y))}{\sum_{j,k} \tilde{\varphi}_j^k(y)} \right) \\ \sum_{i,n} |\nabla\varphi_i^n|(y) &\leq \frac{2(N+1)}{2^n} \cdot \left(\frac{\sum_{j,k} f(\tilde{\varphi}_j^k(y))}{\sum_{j,k} \tilde{\varphi}_j^k(y)} + \frac{\sum_{j,k} \tilde{\varphi}_j^k(y)}{\sum_{j,k} \tilde{\varphi}_j^k(y)} \cdot \frac{\sum_{j,k} f(\tilde{\varphi}_j^k(y))}{\sum_{j,k} \tilde{\varphi}_j^k(y)} \right) \\ &= \frac{4(N+1)}{2^n} \cdot \frac{\frac{1}{K(y)} \sum_{j,k} f(\tilde{\varphi}_j^k(y))}{\frac{1}{K(y)} \sum_{j,k} \tilde{\varphi}_j^k(y)} \leq \frac{4(N+1)}{2^n} \cdot \frac{f\left(\frac{1}{K(y)} \sum_{j,k} \tilde{\varphi}_j^k(y)\right)}{\frac{1}{K(y)} \sum_{j,k} \tilde{\varphi}_j^k(y)} \\ &\leq \frac{4(N+1)}{2^n} \cdot K(y) f\left(\frac{1}{K(y)}\right) \\ &\leq \frac{1}{d(y, X)} \cdot [32\ell(N+1)] K(y) f\left(\frac{1}{K(y)}\right), \end{aligned}$$

where we used the concavity of f , the fact that $f(t)/t$ is decreasing (it follows from $f(0) = 0$ and the concavity), and that $\sum_{j,k} \tilde{\varphi}_j^k(y) \geq 1$ by (d).

Now we choose $\ell = 3$, $\delta = 1/2$, and

$$f(t) = \frac{2m}{\delta} t^{1-1/m}$$

which allows the existence of the function ξ as required before by a simple cutoff argument applied to $\tilde{\xi}(t) = \chi_{[0, \infty)}(t) \left(\frac{2t}{\delta}\right)^m$. From (2.1) we deduce that

$$K(y) \leq 4\kappa_X(1/49) \leq 4\lambda_X^6,$$

we obtain also $N = \kappa_X(2/55) \leq \lambda^5$ and we take $m = \log(4\lambda_X^6)$.

We can now finish the proof by estimating

$$\begin{aligned} \sum_{i,n} |\nabla\varphi_i^n|(y) &\leq \frac{1}{d(y, X)} \cdot 4[96(N+1)]mK(y)^{1/m} \\ &\lesssim \frac{1}{d(y, X)} \cdot \lambda^5 m e^{m/m} = \frac{1}{d(y, X)} \lambda^5 \log(\lambda). \quad \square \end{aligned}$$

3 Random projections

The following concept has been introduced by Ohta [Oht09] and by Ambrosio and Puglisi [AP16]. In these articles the authors identify a generalization of a deterministic projection onto a subset, an idea that underlies several extension results. In order to understand the concept let us suppose that $Y = \mathbb{R}^k$ and $X \subset Y$ is a closed convex set. In this case, for every point $y \in Y$ there exists a unique point of X with minimal distance from y and so we have the projection function $P_X : Y \rightarrow X$ that is the identity on X and is 1-Lipschitz on the whole Y . This map allows to build a linear Lipschitz extension operator $T : \text{Lip}(X) \rightarrow \text{Lip}(Y)$ simply by composition $Tf = f \circ P_X$. Notice that with this definition the Lipschitz constant of f is also preserved. Clearly this kind of construction works only in particular cases, due to topological obstructions. Even in the Euclidean context, the class of subset X that are Lipschitz retractions of the ambient space is very small. In order to overcome this difficulty, we look for non-deterministic maps that share the same features of projections with regard to the possibility of extending functions with the method outlined above. These objects are the so-called random projections, which in some sense are a probabilistic selection of quasi-minimizers of the distance.

Definition 3.1 (Random projection). Let X be a closed subspace of a metric space (Y, d) . We say that a map $\mu : Y \rightarrow \mathcal{P}(X) : y \mapsto \mu_y$ is a *random projection* if $\mu_x = \delta_x$ whenever $x \in X$. We say that it is a *Lipschitz random projection* if $\mu \in \text{Lip}(Y; W_1(X))$.

Theorem 3.2. *Let $X \subset (Y, d)$ be a closed subset with doubling constant λ . Then there exists a Lipschitz random projection $\mu \in \text{Lip}(Y; W_1(X))$ with*

$$\text{Lip}(\mu) \lesssim \log \lambda.$$

Remark 3.3. Notice that any Lipschitz random projection μ gives automatically a bounded linear extension operator $T : \text{Lip}(X, Z) \rightarrow \text{Lip}(Y, Z)$ for every Banach space Z in the following way:

$$(Tf)(y) = \int_X f(x) d\mu_y(x).$$

In fact, thanks to (1.1) we have

$$|(Tf)(y) - (Tf)(y')| = \left| \int_X f(x) d(\mu_y - \mu_{y'}) \right| \leq \text{Lip}(f) \text{Lip}(\mu) d(y, y').$$

Therefore the proof of [Theorem 3.2](#) can be seen as a proof of the existence of a bounded linear extension operator (see [Theorem 4.1](#)).

Proof. Without loss of generality we can assume that Y is a Banach space, by possibly embedding $Y \subset C_b(Y)$ thanks to the isometric immersion

$$y \mapsto d(\cdot, y) - d(\cdot, y_0),$$

where $y_0 \in Y$ is a generic fixed point: this is useful because in order to prove that some function $F : Y \rightarrow Z$ is L -Lipschitz we need only to prove that its slope is bounded by L .

Let $\{V_i, \varphi_i, x_i\}_i$ be given by Proposition 2.1. Let us then define the random projection

$$\mu_y = \sum_i \varphi_i(y) \delta_{x_i} \quad \text{for } y \in Y \setminus X, \quad \mu_y = \delta_y \quad \text{for } y \in X.$$

Given a function $f \in \text{Lip}_1(X)$, for $y \in Y \setminus X$ we can compute the slope

$$\begin{aligned} \left| \nabla_y \int_X f(x) d\mu_y(x) \right| &= \left| \nabla_y \sum_i \varphi_i(y) f(x_i) \right| \\ &= \left| \nabla_y \sum_i \varphi_i(y) [f(x_i) - f(x_{i_0})] \right| \\ &\leq \sum_i |\nabla_y \varphi_i(y)| \cdot |f(x_i) - f(x_{i_0})| \\ &\leq \sum_i |\nabla_y \varphi_i(y)| \cdot d(x_i, x_{i_0}), \end{aligned}$$

where i_0 is any fixed index for which $y \in V_{i_0}$. In order for $|\nabla_y \varphi_i(y)|$ to be non-zero, one must have $y \in V_i$, therefore from the properties of the points x_i 's we infer that $d(x_i, x_{i_0}) \lesssim d(y, X)$. With this observation we can continue the previous estimate and obtain

$$\left| \nabla_y \int_X f(x) d\mu_y(x) \right| \lesssim \sum_i |\nabla_y \varphi_i(y)| \cdot d(y, X) \lesssim \frac{\log \lambda}{d(y, X)} d(y, X) = \log \lambda.$$

For points $x \in X$ and $y \in Y \setminus X$ instead we have the estimate

$$\begin{aligned} \left| \int_X f(z) d\mu_y(z) - \int_X f(z) d\mu_x(z) \right| &= \left| \sum_i \varphi_i(y) [f(x_i) - f(x)] \right| \\ &\leq \sum_i \varphi_i(y) (|f(x_i) - f(x_{i_0})| + |f(x_{i_0}) - f(x)|) \\ &\leq \sum_i \varphi_i(y) [d(x_i, x_{i_0}) + d(x_{i_0}, x)] \\ &\lesssim d(y, X) + d(x_{i_0}, x) \\ &\leq d(y, X) + d(x_{i_0}, y) + d(y, x) \\ &\lesssim d(y, x), \end{aligned}$$

so that we have a (better) bound on the slope also at the points in X . This fact shows that the map $y \mapsto \int_X f d\mu_y$ has Lipschitz constant less than $\log \lambda$, up to a universal multiplicative constant.

Finally, Definition 1.1 of W_1 implies that $\text{Lip}(\mu) \lesssim \log \lambda$, indeed. \square

We now move on to the corresponding C^1 concept of random projection.

Definition 3.4. Let X be a subset of a Banach space Y . We say that a map $\mu : Y \rightarrow \mathcal{P}(X)$ is a *regular random projection* if the following conditions hold:

- (i) for every $y \in Y$ the measure μ_y is concentrated on $B(y, \eta d(y, X))$ for some $\eta > 0$;

(ii) for all $f \in C(X)$ the map $F(y) = \int_X f(x) d\mu_y(x)$ is well defined, belongs to $C(Y) \cap C^1(Y \setminus X)$, and there exists $\nu : Y \setminus X \rightarrow \mathcal{M}(X; Y^*)$ such that

$$dF_y = \int_X f(x) d\nu_y(x) \quad \text{for all } y \in Y \setminus X; \quad (3.1)$$

(iii) for all $y \in Y \setminus X$ the measure ν_y is concentrated on $B(y, \eta d(y, X))$ and its total variation can be estimated with

$$\|\nu_y\|_{\text{TV}} \leq \frac{C_X}{d(y, X)}.$$

Remark 3.5. With the definition above we have that $\nu_x(X) = 0$ for all $x \in Y \setminus X$, since

$$\nu_y(X) = \int_X 1 d\nu_y = d\left(\int_X 1 d\mu_x\right)_y = d1_y = 0.$$

Theorem 3.6 (Regular random projection). *Let Y be a Banach space whose norm belongs to $C^1(Y \setminus \{0\})$ and let $X \subset Y$ be a closed subset with doubling constant λ . Then there exists a regular random projection μ_y whose associated ν_y has total variation*

$$\|\nu_y\|_{\text{TV}} \lesssim \frac{\lambda^4 \log \lambda}{d(y, X)}.$$

Proof. Let $\{V_i, \varphi_i, x_i\}_i$ be given by [Proposition 2.2](#). Let us then define the random projection

$$\mu_y = \sum_i \varphi_i(y) \delta_{x_i} \quad \text{for } y \in Y \setminus X, \quad \mu_y = \delta_y \quad \text{for } y \in X.$$

Property (i) of [Definition 3.4](#) follows immediately from (iii) of [Proposition 2.2](#). Let us fix $f \in C(X)$. The function $F(y) = \int_X f(x) d\mu_y(x)$ is clearly well defined since the measure μ_y is supported on a finite number of points. Moreover, it is also $C^1(Y \setminus X)$ because the coefficients $\varphi_i(y)$ are C^1 themselves. Given a point $y \in Y \setminus X$, it is immediate to check that the differential of F at the point y is represented through (3.1) by the vector measure

$$\nu_y = \sum_i d(\varphi_i)_y \delta_{x_i}.$$

Finally, (iii) of [Definition 3.4](#) follows from (ii) of [Proposition 2.2](#). □

4 Linear extension operators

4.1 Lipschitz

In this section we state and prove the main result about the extendability of Lipschitz functions. The theorem has already appeared in [\[LN05\]](#), but we provide two independent and shorter proofs.

Theorem 4.1. *Let (Y, d) be a metric space and $X \subset Y$ a closed subset with finite doubling constant λ ; let moreover Z be a Banach space. Then there exists a linear extension operator $T : \text{Lip}(X; Z) \rightarrow \text{Lip}(Y; Z)$ such that*

$$\text{Lip}(Tf) \lesssim \log \lambda \text{Lip}(f) \quad \forall f \in \text{Lip}(X; Z).$$

As already observed in Remark 3.3, this result can be obtained already as a direct consequence of Theorem 3.2, but we wanted also to provide a self-contained proof that does not require the construction of a partition of unity, but instead exploits the existence of a doubling measure \mathbf{m} supported on the whole X .

Direct proof. Without loss of generality we can assume that Y is a Banach space, by embedding $Y \subset C_b(Y)$ thanks to the isometric immersion

$$y \mapsto d(\cdot, y) - d(\cdot, y_0),$$

where $y_0 \in Y$ is a fixed point. In particular we can assume that also X is complete by considering its new closure. Let \mathbf{m} be a doubling measure on X , provided for instance by [VK88]. We consider the random projection $\mu : Y \rightarrow \mathcal{P}(X)$ absolutely continuous with respect to \mathbf{m} given by

$$\mu_y = u_y(x)\mathbf{m} = \frac{\varphi^m\left(\frac{d(y,x)}{d(y,X)}\right)}{\int_X \varphi^m\left(\frac{d(y,z)}{d(y,X)}\right) d\mathbf{m}(z)} \mathbf{m},$$

where $\varphi \in C^1([0, \infty); [0, 1])$ is such that $\varphi(t) = 1$ for $t \leq 2$, $\varphi(t) = 0$ for $t \geq 3$ and $m > 0$ is a parameter to be optimized later. Notice that the denominator is non-zero because \mathbf{m} is doubling. Roughly speaking, this μ has to be intended as a suitably smoothed version of

$$\tilde{\mu}_y = \frac{\mathbf{m} \llcorner B(y, 3d(y, X))}{\mathbf{m}(B(y, 3d(y, X)))}.$$

Given a function $f \in \text{Lip}(X; Z)$, we define its extension Tf by

$$Tf(y) = \int_X f(x) d\mu_y(x).$$

In order to compute $\text{Lip}(Tf)$, we now proceed by estimating the slope of the density u_y .

By Leibniz and Fatou³ we have

$$|\nabla_y u_y(x)| \leq \frac{\left| \nabla_y \varphi^m\left(\frac{d(y,x)}{d(y,X)}\right) \right|}{\int_X \varphi^m\left(\frac{d(y,z)}{d(y,X)}\right) d\mathbf{m}(z)} + \frac{\varphi^m\left(\frac{d(y,x)}{d(y,X)}\right) \int_X \left| \nabla_y \varphi^m\left(\frac{d(y,z)}{d(y,X)}\right) \right| d\mathbf{m}(z)}{\left[\int_X \varphi^m\left(\frac{d(y,z)}{d(y,X)}\right) d\mathbf{m}(z) \right]^2}$$

³To apply the latter in order to pass the slope inside the integral, we need also that

$$\sup_{\substack{z \in X \\ d(y,y') < \frac{1}{2}d(y,X)}} \frac{1}{d(y,y')} \left| \varphi^m\left(\frac{d(y',z)}{d(y',X)}\right) - \varphi^m\left(\frac{d(y,z)}{d(y,X)}\right) \right| < \infty.$$

Integrating in x and simplifying we obtain

$$\int_X |\nabla_y u_y(x)| \, \mathrm{d}\mathbf{m}(x) = 2 \frac{\int_X \left| \nabla_y \varphi^m \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \right| \, \mathrm{d}\mathbf{m}(z)}{\int_X \varphi^m \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \, \mathrm{d}\mathbf{m}(z)}.$$

One can then compute

$$\begin{aligned} \left| \nabla_y \varphi^m \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \right| &\leq m \varphi^{m-1} \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \left| \varphi' \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \right| \cdot \left| \nabla_y \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \right| \\ &\leq m \varphi^{m-1} \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \left| \varphi' \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \right| \frac{1}{\mathbf{d}(y,X)} \left(1 + \frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right). \end{aligned}$$

Plugging this into the previous equation, observing that the ratio $\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} < 3$ where φ is not vanishing and using Hölder inequality in the second step⁴ we get

$$\begin{aligned} \int_X |\nabla_y u_y(x)| \, \mathrm{d}\mathbf{m}(x) &\leq \frac{8m}{\mathbf{d}(y,X)} \cdot \frac{\int_X \varphi^{m-1} \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \left| \varphi' \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \right| \, \mathrm{d}\mathbf{m}(z)}{\int_X \varphi^m \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \, \mathrm{d}\mathbf{m}(z)} \\ &\leq \frac{8m}{\mathbf{d}(y,X)} \left(\frac{\int_X \left| \varphi' \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \right|^m \, \mathrm{d}\mathbf{m}(x)}{\int_X \varphi^m \left(\frac{\mathbf{d}(y,z)}{\mathbf{d}(y,X)} \right) \, \mathrm{d}\mathbf{m}(x)} \right)^{1/m} \\ &\leq \frac{8m}{\mathbf{d}(y,X)} \left(\frac{\mathbf{m}(B(y, 3\mathbf{d}(y,X)))}{\mathbf{m}(B(y, 2\mathbf{d}(y,X)))} \right)^{1/m}. \end{aligned}$$

The ratio appearing in the last formula is related to the doubling constant λ , however one has to be a bit careful because the point y does not belong to X . By fixing a point $\tilde{y} \in X$ such that $\mathbf{d}(y, \tilde{y}) \leq (1 + \varepsilon)\mathbf{d}(y, X)$ we get

$$\frac{\mathbf{m}(B(y, 3\mathbf{d}(y, X)))}{\mathbf{m}(B(y, 2\mathbf{d}(y, X)))} \leq \frac{\mathbf{m}(B(\tilde{y}, (4 + \varepsilon)\mathbf{d}(y, X)))}{\mathbf{m}(B(\tilde{y}, (1 - \varepsilon)\mathbf{d}(y, X)))} \leq \lambda^3.$$

Hence

$$\int_X |\nabla_y u_y(x)| \, \mathrm{d}\mathbf{m}(x) \lesssim \frac{m\lambda^{3/m}}{\mathbf{d}(y, X)} \lesssim \frac{\log \lambda}{\mathbf{d}(y, X)}$$

by choosing $m = \frac{1}{3} \log \lambda$.

We can finally estimate the Lipschitz constant of Tf . We start with its slope at

⁴With exponents $m/(m-1)$ and m .

$y \in Y \setminus X$. Fixing a point $\tilde{y} \in X$ such that $d(y, \tilde{y}) \lesssim d(y, X)$, we have

$$\begin{aligned}
|\nabla T f|(y) &\leq \left| \nabla_y \int_X [f(x) - f(\tilde{y})] d\mu_y(x) \right| \\
&\leq \int_{B(y, 3d(y, X))} |f(x) - f(\tilde{y})| \cdot |\nabla_y u_y(x)| d\mathbf{m}(x) \\
&\lesssim \int_{B(y, 3d(y, X))} \text{Lip}(f)[d(x, y) + d(y, \tilde{y})] \frac{\log \lambda}{d(y, X)} d\mu_y(x) \\
&\lesssim \text{Lip}(f)d(y, X) \frac{\log \lambda}{d(y, X)} \\
&\lesssim \log \lambda \text{Lip}(f),
\end{aligned}$$

where we were able to bring the slope inside the integral because the difference ratios near y are uniformly bounded in x . Similarly, for $x \in X$ and $y \in Y \setminus X$ one can compute

$$\begin{aligned}
|T f(y) - T f(x)| &\leq \int_X |f(z) - f(x)| d\mu_y(z) \\
&\leq \text{Lip}(f) \int_{B(y, 3d(y, X))} d(z, x) d\mu_y(z) \\
&\leq \text{Lip}(f) \int_{B(y, 3d(y, X))} [d(z, y) + d(y, x)] d\mu_y(z) \\
&\lesssim \text{Lip}(f)[d(y, X) + d(y, x)] \\
&\lesssim \text{Lip}(f)d(x, y)
\end{aligned}$$

These two computations prove the Lipschitzianity of the map $T f$, with constant $\text{Lip}(T f) \lesssim \log \lambda \text{Lip}(f)$, since the space Y is Banach. \square

Remark 4.2. Actually, the previous proof is an alternative self-contained construction of a Lipschitz random projection μ that does not use a Lipschitz partition of unity.

4.2 Whitney

The goal of this section is to generalize Whitney's extension theorem [Whi34] to Banach spaces.

Let Y be a Banach space and let $X \subset Y$ be a closed subset of X , we assume that $f : X \rightarrow \mathbb{R}$ and $L : X \rightarrow Y^*$ are given functions. We define

$$R(x, y) = f(y) - f(x) - L_x(y - x) \quad x, y \in X.$$

Our aim is to find conditions on R and X in order to have a C^1 extension of f at the whole Y and we want that its differential coincides with L in X . The classical Whitney's extension theorem ensures that when $Y = \mathbb{R}^n$ and $R(x, y) = o(|x - y|)$ in a suitable sense then the C^1 extension there exists. Our result is the following:

Theorem 4.3. *Let Y be a Banach space whose norm belongs to $C^1(Y \setminus \{0\})$ and let $X \subset Y$ be a closed subset with doubling constant λ . Given two continuous functions $f : X \rightarrow \mathbb{R}$ and $L : X \rightarrow Y^*$, define the remainder*

$$R(x, y) = f(y) - f(x) - L_x(y - x) \quad \text{for } x, y \in X, x \neq y$$

and assume that the function

$$(x, y) \mapsto \frac{R(x, y)}{|y - x|}$$

can be extended to a continuous function on $X \times X$ that takes the value 0 where $y = x$. Then there exists an extension $\tilde{f} \in C^1(Y)$ such that $d\tilde{f}_x = L_x$ for all $x \in X$.

Moreover, the extension operator $(f, L) \mapsto \tilde{f}$ is linear.

First we prove a key lemma, that is an integral version of $R(x, y) = o(|x - y|)$, given our hypothesis on R .

Lemma 4.4. *Let $\bar{\mu} : Y \rightarrow \mathcal{M}_+(X)$ be a weakly measurable map such that $|\bar{\mu}_y|(X) \leq 1$ and there exists $C > 0$ such that $\text{supp } \bar{\mu}_y \in B(y, Cd(y, X))$ for all $y \in Y$. Assuming the hypothesis of the [Theorem 4.3](#), for all $x \in X$ we have*

$$\int_X |R(z, x)| d\bar{\mu}_y(z) = o(|x - y|) \quad \text{as } y \rightarrow x.$$

Proof. Let $\tilde{y} \in X$ be a point such that $|y - \tilde{y}| \leq 2d(y, X)$. We can estimate

$$\begin{aligned} |R(z, x)| &\leq |R(z, x) - R(z, \tilde{y})| + |R(z, \tilde{y})| \\ &= |f(\tilde{y}) - f(x) - L_z(\tilde{y} - x)| + |R(z, \tilde{y})| \\ &\leq |f(\tilde{y}) - f(x) - L_x(\tilde{y} - x)| + |(L_z - L_x)(\tilde{y} - x)| + |R(z, \tilde{y})| \\ &\leq |R(x, \tilde{y})| + \|L_z - L_x\| |\tilde{y} - x| + |R(z, \tilde{y})|. \end{aligned}$$

We observe that

$$|\tilde{y} - x| \leq |\tilde{y} - y| + |y - x| \leq 2d(y, X) + |y - x| \leq 3|y - x|, \quad (4.1)$$

therefore we have

$$\int_X |R(z, x)| d\bar{\mu}_y(z) \leq \underbrace{|R(x, \tilde{y})|}_A + 3|y - x| \underbrace{\int_X |L_z - L_x| d\bar{\mu}_y(z)}_B + \underbrace{\int_X |R(z, \tilde{y})| d\bar{\mu}_y(z)}_C.$$

We analyze each contribution separately.

(A) Using (4.1) and the continuity of $(x, y) \mapsto R(x, y)/|x - y|$ we have

$$\frac{|R(x, \tilde{y})|}{|x - y|} \leq 3 \frac{|R(x, \tilde{y})|}{|x - \tilde{y}|} \rightarrow 0.$$

(B) The term $\int_X |L_z - L_x| d\bar{\mu}_y(z)$ is infinitesimal as y goes to x because the map $z \mapsto |L_z - L_x|$ is continuous and $\text{supp } \bar{\mu}_y \in B(y, Cd(y, X))$.

(C) We can estimate

$$\begin{aligned}
\int_X |R(z, \tilde{y})| d\bar{\mu}_y(z) &= \int_{X \cap B(y, Cd(y, X))} |R(z, \tilde{y})| d\bar{\mu}_y(z) \\
&= \int_{X \cap B(y, Cd(y, X))} |z - \tilde{y}| \frac{|R(z, \tilde{y})|}{|z - \tilde{y}|} d\bar{\mu}_y(z) \\
&\leq \int_X |\tilde{y} - y| \frac{|R(z, \tilde{y})|}{|z - \tilde{y}|} d\bar{\mu}_y(z) \\
&\quad + \int_{X \cap B(y, Cd(y, X))} |y - z| \frac{|R(z, \tilde{y})|}{|z - \tilde{y}|} d\bar{\mu}_y(z) \\
&\leq |\tilde{y} - y| \int_X \frac{|R(z, \tilde{y})|}{|z - \tilde{y}|} d\bar{\mu}_y(z) \\
&\quad + Cd(y, X) \int_X \frac{|R(z, \tilde{y})|}{|z - \tilde{y}|} d\bar{\mu}_y(z) \\
&\leq (2 + C)|y - x| \int_X \frac{|R(z, \tilde{y})|}{|z - \tilde{y}|} d\bar{\mu}_y(z).
\end{aligned}$$

Finally we observe that again using (4.1) we have $\tilde{y} \rightarrow x$ and thanks to the continuity of $(x, y) \mapsto R(x, y)/|x - y|$ we have

$$\int_X \frac{|R(z, \tilde{y})|}{|z - \tilde{y}|} d\bar{\mu}_y(z) \leq \sup_{z \in B(y, Cd(y, X)) \cap X} \frac{|R(z, \tilde{y})|}{|z - \tilde{y}|} \rightarrow 0. \quad \square$$

Proof of Theorem 4.3. Let μ be a regular random projection as provided by Theorem 3.6. We define the extension of f as

$$\tilde{f}(y) = \int_X [f(z) + L_z(y - z)] d\mu_y(z). \quad (4.2)$$

We first prove that the function \tilde{f} is differentiable at any point $x \in X$ and that $d\tilde{f}_x = L_x$. Indeed, we have

$$\begin{aligned}
|\tilde{f}(y) - \tilde{f}(x) - L_x(y - x)| &= \left| \int_X [f(z) + L_z(y - z)] d\mu_y(z) - f(x) - L_x(y - x) \right| \\
&\leq \left| \int_X [f(x) - f(z) - L_z(x - z)] d\mu_y(z) \right| \\
&\quad + \left| \int_X (L_z - L_x)(y - x) d\mu_y(z) \right| \\
&\leq \int_X |R(z, x)| d\mu_y(z) + |y - x| \int_X |L_z - L_x| d\mu_y(z),
\end{aligned}$$

the last term is $o(|y - x|)$ thanks to Lemma 4.4 and the continuity of L .

Now we observe that $\tilde{f} \in C^1(Y \setminus X)$ and

$$d\tilde{f}_y = \int_X L_z d\mu_y(z) + \int_X [f(z) + L_z(y - z)] d\nu_y(z) \quad \forall y \in Y \setminus X$$

by a simple differentiation of (4.2) and using (ii) of Definition 3.4.

In order to conclude the proof we have to check that $y \mapsto d\tilde{f}_y$ is a continuous map from Y to Y^* . We already know that the differential of \tilde{f} is continuous on the open set $Y \setminus X$ and when it is restricted to X , therefore it is enough to estimate $|d\tilde{f}_y - d\tilde{f}_x|$ with $y \in Y \setminus X$ and $x \in X$. Fixing a point $\tilde{y} \in X$ such that $|y - \tilde{y}| \leq 2d(y, X)$, we have

$$\begin{aligned} |d\tilde{f}_y - d\tilde{f}_x| &\leq |d\tilde{f}_y - d\tilde{f}_{\tilde{y}}| + |d\tilde{f}_{\tilde{y}} - d\tilde{f}_x| \\ &= |d\tilde{f}_y - d\tilde{f}_{\tilde{y}}| + |L_{\tilde{y}} - L_x|. \end{aligned}$$

Now we estimate the first term as

$$\begin{aligned} |d\tilde{f}_y - d\tilde{f}_{\tilde{y}}| &= \left| \left(\int_X L_z d\mu_y(z) + \int_X [f(z) + L_z(y - z)] d\nu_y(z) \right) - L_{\tilde{y}} \right| \\ &\leq \left| \int_X f(z) + L_z(y - z) d\nu_y(z) \right| + \left| \int_X L_z d\mu_y(z) - L_{\tilde{y}} \right| \\ &\leq \left| \int_X f(z) + L_z(y - z) d\nu_y(z) \right| + \int_X |L_z - L_{\tilde{y}}| d\mu_y(z). \end{aligned}$$

Recalling Remark 3.5 we have

$$\begin{aligned} \left| \int_X f(z) + L_z(y - z) d\nu_y(z) \right| &= \left| \int_X f(z) - f(\tilde{y}) - L_z(z - \tilde{y}) d\nu_y(z) \right| \\ &\quad + \left| \int_X L_z(y - \tilde{y}) d\nu_y(z) \right| \\ &\leq \int_X |R(z, \tilde{y})| d|\nu_y|(z) + |y - \tilde{y}| \int_X |L_z - L_{\tilde{y}}| d|\nu_y|(z). \end{aligned}$$

Using the property (iii) in Definition 3.4 we can write $|\nu_y| = \frac{C}{d(y, X)} \bar{\mu}_y$ and we notice that $\bar{\mu}_y$ satisfies the hypothesis in Lemma 4.4. Moreover recalling the assumption $|y - \tilde{y}| \leq 2d(y, X)$ we have

$$\begin{aligned} \left| \int_X f(z) + L_z(y - z) d\nu_y(z) \right| &\leq \frac{C}{d(y, X)} \int_X |R(z, \tilde{y})| d\bar{\mu}_y(z) + \frac{C|y - \tilde{y}|}{d(y, X)} \int_X |L_z - L_{\tilde{y}}| d\bar{\mu}_y(z) \\ &\leq \frac{2C}{|\tilde{y} - y|} \int_X |R(z, \tilde{y})| d\bar{\mu}_y(z) + 2C \int_X |L_z - L_{\tilde{y}}| d\bar{\mu}_y(z). \end{aligned}$$

Finally putting all together

$$|d\tilde{f}_y - d\tilde{f}_x| \leq |L_{\tilde{y}} - L_x| + (2C + 1) \int_X |L_z - L_{\tilde{y}}| d\mu_y(z) + \frac{2C}{|\tilde{y} - y|} \int_X |R(z, \tilde{y})| d\bar{\mu}_y(z).$$

Recalling $|x - \tilde{y}| \leq 3|x - y|$ and Lemma 4.4 we conclude that $|d\tilde{f}_y - d\tilde{f}_x| \rightarrow 0$ when y goes to x . This shows that $d\tilde{f}$ is continuous also in every point of X and concludes the proof. \square
